CHAPTER 5

FUNCTION DEFINITION, MANIPULATION, AND EVALUATION

The Interlisp programming system is designed to help the user de ne and debug functions. Developing an applications program in Interlisp involves de ning a number of functions in terms of the system primitives and other user-de ned functions. Once de ned, the user's functions may be referenced exactly like Interlisp primitive functions, so the programming process can be viewed as extending the Interlisp language to include the required functionality.

The user de nes a function with a list expressions known as an EXPR. An EXPR species if the function has a xed or variable number of arguments, whether these arguments are evaluated or not, the function argument names, and a series of forms which de ne the behavior of the function. For example:

```
(LAMBDA (X Y) (PRINT X) (PRINT Y))
```

A function de ned with this EXPR would have two evaluated arguments, X and Y, and it would execute (PRINT X) and (PRINT Y) when evaluated. Other types of EXPRs are described below.

A function is defined by putting an EXPR in the function definition cell of a litatom. There are a number of functions for accessing and setting function definition cells, but one usually defines a function with DEFINEQ (page 5.9). For example:

```
_ (DEFINEQ (FOO (LAMBDA (X Y) (PRINT X) (PRINT Y))
(FOO)
```

The expression above will de ne the function FOO to have the EXPR de nition (LAMBDA (X Y) (PRINT X) (PRINT Y)). After being de ned, this function may be evaluated just like any system function:

```
_ (FOO 3 (IPLUS 3 4))
3
7
7
```

All function de nition cells do not contain EXPRs. The compiler (page 12.1) translates EXPR de nitions into compiled code objects, which execute much faster. In Interlisp- 10, many primitive system functions are de ned with machine code objects known as SUBRs. Interlisp provides a number of "function type functions" which determine how a given function is de ned (EXPR/compiled code/ SUBR), the number and names of function arguments, etc. See page 5.6.

Usually, functions are evaluated automatically when they appear within another function or when typed into Interlisp. However, sometimes it is useful to envoke the Interlisp interpreter explicitly to apply a given "functional argument" to some data. There are a number of functions which will apply a given function repeatedly. For example, MAPCAR will apply a function (or an EXPR) to all of the elements of a list, and return the values returned by the function:

```
_ (MAPCAR '(1 2 3 4 5) '(LAMBDA (X) (ITIMES X X))
```

Function Types

(1 4 9 16 25)

When using functional arguments, there are a number of problems which can arise, related with accessing free variables from within a function argument. Many times these problems can be solved using the function FUNCTION to create a FUNARG object (see page 5.15).

The macro facility provides another way of specifying the behavior of a function (see page 5.17). Macros are very useful when developing code which should run very quickly, which should be compiled dierently than it is interpreted, or which should run dierently in dierent implementations of Interlisp.

5.1 FUNCTION TYPES

Interlisp functions are defined using list expressions called EXPRs. An EXPR is a list of the form (LAMBD A-W ORD AR G-LIST FORM $_1$ FORM $_N$). LAMBD A-W ORD determines whether the arguments to this function will be evaluated or not, ar g-list determines the number and names of arguments, and FORM $_1$ FORM $_N$ are a series of forms to be evaluated after the arguments are bound to the local variables in AR g-list.

If LAMBD A-W ORD is the litatom LAMBDA, then the arguments to the function are evaluated. If LAMBD A-W ORD is the litatom NLAMBDA, then the arguments to the function are not evaluated. Functions which evaluate or don't evaluate their arguments are therefore known as "lambda" or "nlambda" functions, respectively.

If AR G-LIST is NIL or a list of litatoms, this indicates a function with a xed number of arguments. Each litatom is the name of an argument for the function de ned by this expression. The process of binding these litatoms to the individual arguments is called "spreading" the arguments, and the function is called a "spread" function. If the argument list is any litatom other than NIL, this indicates a function with a variable number of arguments, known as a "nospread" function.

If AR G-LIST is anything other than a litatom or a list of litatoms, such as (LAMBDA "FOO"), attempting to use this EXPR will generate an ARG NOT LITATOM error. In addition, if NIL or T is used as an argument name, the error ATTEMPT TO BIND NIL OR T is generated.

These two parameters (lambda/nlambda and spread/nospread) may be specied independently, so there are four main function types, known as lambda-spread, nlambda-spread, lambda-nospread, and nlambda-nospread functions. Each one has a dierent form, and is used for a dierent purpose. These four function types are described more fully below.

Note: The Lambdatran lispusers package provides facilities for creating new function types which evaluate/spread their arguments in di erent ways than those provided by Interlisp. See page 23.16.

5.1.1 Lambda-Spread Functions

Lambda- spread functions take a xed number of evaluated arguments. This is the most common function type. A lambda- spread EXPR has the form:

(LAMBDA (arg
$$_1$$
 arg $_M$) form $_1$ form $_N$)

The argument list (arg_largement list of litatoms that gives the number and names of the formal arguments to the function. If the argument list is () or NIL, this indicates that the function takes no arguments. When a lambda-spread function is applied to some arguments, the arguments are evaluated, and bound to the local variables arg_largement arg_largements. Then, form largements are evaluated in order, and the value of the function is the value of form largement list of litatoms that gives the number and names of the formal arguments to the function takes no arguments. When a lambda-spread function is applied to some arguments, the arguments are evaluated, and bound to the local variables arg_largement list of litatoms that gives the number and names of the formal arguments.

```
_ (DEFINEQ (FOO (LAMBDA (X Y) (PRINT X) (PRINT Y))) )
(FOO)
_ (FOO 99 (PLUS 3 4))
99
7
7
```

In the above example, the function FOO de ned by (LAMBDA (X Y) (PRINT X) (PRINT Y)) is applied to the arguments 99 and (PLUS 3 4), these arguments are evaluated (giving 99 and 7), the local variable X is bound to 99 and Y to 7, (PRINT X) is evaluated, printing 99, (PRINT Y) is evaluated, printing 7, and 7 (the *value* of (PRINT Y)) is returned as the value of the function.

A standard feature of the Interlisp system is that no error occurs if a spread function is called with too many or too few arguments. If a function is called with too many arguments, the extra arguments are evaluated but ignored. If a function is called with too few arguments, the unsupplied ones will be delivered as NIL. In fact, a spread function cannot distinguish between being given NIL as an argument, and not being given that argument, e.g., (FOO) and (FOO NIL) are *exactly* the same for spread functions. If it is necessary to distinguish between these two cases, use an nlambda function and explicitly evaluate the arguments with the EVAL function (page 5.11).

5.1.2 Nlambda-Spread Functions

Nlambda- spread functions take a xed number of unevaluated arguments. An nlambda- spread EXPR has the form:

```
(NLAMBDA (arg _1 arg _M) form _1 form _N)
```

Nlambda- spread functions are evaluated similarly to lambda- spread functions, except that the arguments are not evaluated before being bound to the variables ARG_1 ARG_M .

```
_ (DEFINEQ (FOO (NLAMBDA (X Y) (PRINT X) (PRINT Y))) )
(FOO)
_ (FOO 99 (PLUS 3 4))
99
(PLUS 3 4)
(PLUS 3 4)
```

In the above example, the function FOO de ned by (NLAMBDA (X Y) (PRINT X) (PRINT Y)) is applied to the arguments 99 and (PLUS 3 4), these arguments are bound unevaluated to X and Y, (PRINT X) is evaluated, printing 99, (PRINT Y) is evaluated, printing (PLUS 3 4), and the list (PLUS 3 4) is returned as the value of the function.

Note: Functions can be de ned so that all of their arguments are evaluated (lambda functions) or none

Lambda-Nospread Functions

are evaluated (nlambda functions). If it is desirable to write a function which only evaluates *some* of its arguments (e.g. SETQ), the function should be defined as an nlambda, with some arguments explicitly evaluated using the function EVAL (page 5.11). If this is done, the user should put the litatom EVAL on the property list of the function under the property INFO. This informs various system packages such as DWIM, CLISP, and Masterscope that this function in fact *does* evaluate its arguments, even though it is an nlambda.

5.1.3 Lambda-Nospread Functions

Lambda- nospread functions take a variable number of evaluated arguments. A lambda- nospread EXPR has the form:

```
(LAMBDA var form _1 form _N)
```

VAR may be any litatom, except NIL and T. When a lambda-nospread function is applied to some arguments, each of these arguments is evaluated and the values stored on the pushdown list. VAR is then bound to the number of arguments which have been evaluated. For example, if FOO is de ned by (LAMBDA X), when (FOO A B C) is evaluated, A, B, and C are evaluated and X is bound to 3. VAR should never be reset.

The following functions are used for accessing the arguments of lambda-nospread functions:

```
(ARG VAR M) [NLambda Function]
```

Returns the M th argument for the lambda-nospread function whose argument list is VAR . VAR is the *name* of the atomic argument list to a lambda-nospread function, and is not evaluated; M is the number of the desired argument, and is evaluated. The value of ARG is unde ned for M less than or equal to 0 or greater than the *value* of VAR .

```
(SETARG VAR M X) [NLambda Function]
```

Sets the Mth argument for the lambda-nospread function whose argument list is VAR to X. VAR is not evaluated; M and X are evaluated. M should be between 1 and the value of VAR.

In the example below, the function FOO is de ned to print all of the evaluated arguments it is given, and return NIL (the value of the for statement).

```
_ (DEFINEQ (FOO (LAMBDA X) (for ARGNUM from 1 to X do (PRINT (ARG X ARGNUM)))))))) (FOO)
_ (FOO 99 (PLUS 3 4))
99
7
NIL
_ (FOO 99 (PLUS 3 4) (TIMES 3 4))
99
7
12
NIL
```

5.1.4 **Nlambda-Nospread Functions**

Nlambda- nospread functions take a variable number of unevaluated arguments. An nlambda- nospread EXPR has the form:

```
(NLAMBDA VAR FORM 1
                             FORM <sub>N</sub>)
```

VAR may be any litatom, except NIL and T. Though similar in form to lambda-nospread EXPRs, an nlambda- nospread is evaluated quite di erently. When an nlambda- nospread function is applied to some arguments, VAR is simply bound to a list of the unevaluated arguments. The user may pick apart this list, and evaluate di erent arguments.

In the example below, FOO is de ned to print (and then return) the reverse of list of arguments it is given (unevaluated):

```
_ (DEFINEQ (FOO (NLAMBDA X (REVERSE X))))
(FOO)
_ (FOO 99 (PLUS 3 4))
((PLUS 3 4) 99)
((PLUS 3 4) 99)
(FOO 99 (PLUS 3 4) (TIMES 3 4))
((TIMES 3 4) (PLUS 3 4) 99)
((TIMES 3 4) (PLUS 3 4) 99)
```

5.1.5 **Compiled Functions**

Functions de ned by EXPRs can be compiled by the Interlisp compiler (page 12.1), which produces compiled code objects, which execute more quickly than the corresponding EXPR code. Functions de ned by compiled code objects may have the same four types as EXPRs (lambda/nolambda, spread/nospread). Functions created by the compiler are referred to as compiled functions.

5.1.6 **SUBRs**

In Interlisp- 10, basic built-in functions such as CONS, CAR, and COND are handcoded in machine language. These functions are known as 'SUBRs.'' Functions de ned as SUBRs can be lambda/nolambda or spread/nospread, the same four function types as EXPR functions.

SUBRs are called in a special way, so their denitions are stored dierently than those of compiled or interpreted functions. GETD of a SUBR returns a dotted pair, CAR of which is an encoding of the ARGTYPE and number of arguments of the SUBR, and CDR of which is the address of the rst instruction. Note that each GETD of a subr performs a CONS. Similarly, PUTD of a de nition of the form (NUMBER ADDRESS), where NUMBER and ADDRESS are in the appropriate ranges, stores the de nition as a SUBR.

Function Type Functions

5.1.7 Function Type Functions

There are a variety of functions used for examining the type, argument list, etc. of functions. These functions may be given either a litatom, in which case they obtain the function de nition from the litatom's de nition cell, or a function de nition itself.

(FNTYP FN) [Function]

Returns NIL if FN is not a function de nition or the name of a de ned function. Otherwise FNTYP returns one of the following twelve litatoms:

	Expressions	Compiled	Built-In
Lambda- Spread	EXPR	CEXPR	SUBR
Nlambda- Spread	FEXPR	CFEXPR	FSUBR
Lambda- Nospread	EXPR*	CEXPR*	SUBR*
Nlambda- Nospread	FEXPR*	CFEXPR*	FSUBR*

The types in the rst column are all de ned by EXPRs. The types in the second column are compiled versions of the types in the rst column, as indicated by the pre x C. In the third column are the parallel types for built-in subroutines (only in Interlisp- 10). Functions of types in the rst two rows have a xed number of arguments, i.e., are spread functions. Functions in the third and fourth rows have an inde nite number of arguments, as indicated by the sux *. The pre x F indicates unevaluated arguments. Thus, for example, a CFEXPR* is a compiled nospread-nlambda function.

FNTYP returns the litatom FUNARG if FN is a FUNARG expression. See page 5.15.

(EXPRP FN) [Function]

Returns T if (FNTYP FN) is either EXPR, FEXPR, EXPR*, or FEXPR*, i.e., rst column of FNTYPs; NIL otherwise. However, (EXPRP FN) is also true if FN is (has) a list de nition that is not a SUBR, even if it does not begin with LAMBDA or NLAMBDA. In other words, EXPRP is not quite as selective as FNTYP.

(CCODEP FN) [Function]

Returns T if (FNTYP FN) is either CEXPR, CFEXPR, CEXPR*, or CFEXPR*, i.e., second column of FNTYPs; NIL otherwise.

(SUBRP FN) [Function]

Returns T if (FNTYP FN) is either SUBR, FSUBR, SUBR*, or FSUBR*, i.e., the third column of FNTYPS; NIL otherwise.

(ARGTYPE FN) [Function]

FN is the name of a function or its denition. ARGTYPE returns 0, 1, 2, or 3, or NIL if FN is not a function. The interpretation of this value is:

0 lambda- spread functions (EXPR, CEXPR, SUBR)

- 1 nlambda- spread functions (FEXPR, CFEXPR, FSUBR)
- 2 lambda- nospread functions (EXPR*, CEXPR*, SUBR*)
- 3 nlambda- nospread functions (FEXPR*, CFEXPR*, FSUBR*)

i.e., ARGTYPE corresponds to the rows of FNTYP's.

(NARGS FN)

[Function]

Returns the number of arguments of FN, or NIL if FN is not a function. If FN is a nospread function, the value of NARGS is 1.

(ARGLIST FN)

[Function]

Returns the "argument list" for FN. Note that the "argument list" is a litatom for nospread functions. Since NIL is a possible value for ARGLIST, an error is generated, ARGS NOT AVAILABLE, if FN is not a function.

If FN is a compiled function, the argument list is constructed, i.e., each call to ARGLIST requires making a new list. For EXPRs, whose denitions are lists beginning with LAMBDA or NLAMBDA, the argument list is simply CADR of GETD. If FN has a list denition, and CAR of the denition is not LAMBDA or NLAMBDA, ARGLIST will check to see if CAR of the denition is a member of LAMBDASPLST (page 15.12). If it is, ARGLIST presumes this is a function object the user is dening via DWIMUSERFORMS (page 15.10), and simply returns CADR of the denition as its argument list. Otherwise ARGLIST generates an error as described above.

(Interlisp-10) If FN is a spread SUBR, the ARGLIST returns (U), (U V), (U V W), etc. depending on the number of arguments; if a nospread SUBR, it returns U. This is merely a "feature" of ARGLIST; SUBRs do not actually store the names of their arguments(s) on the stack.

(SMARTARGLIST FN EXPLAINFL G TAIL)

[Function]

A "smart" version of ARGLIST that tries various strategies to get the arglist of FN.

If FN is not defined as a function, SMARTARGLIST attempts spelling correction on FN by calling FNCHECK (page 15.19), passing TAIL to be used for the call to FIXSPELL. If unsuccessful, an error will be generated, FN NOT A FUNCTION.

If FN is known to the le package (page 11.1) but not loaded in, SMARTARGLIST will obtain the arglist information from the le.

In Interlisp- 10, if the HELPSYS help system is installed, SMARTARGLIST may use it to look up the arguments to FN in the Interlisp manual les. Speci cally, HELPSYS will be used if EXPLAINFL G=T and FN is a nospread function, or if FN is a spread SUBR, regardless of the value of EXPLAINFL G. For all other cases, and when HELPSYS is unde ned or unsuccessful in nding the arguments, SMARTARGLIST simply returns (ARGLIST FN).

In order to avoid repeated calls to HELPSYS, and also to provide the user with an override, SMARTARGLIST stores the arguments returned from HELPSYS on the property list of FN under the property ARGNAMES and checks for this property before calling HELPSYS. For spread functions, the argument list itself is stored.

Function De nition

For nospread, the form is (NIL arglist $_1$. Arglist $_2$) where arglist $_1$ is the value of SMARTARGLIST when explainfl g= T, and arglist $_2$ the value when explainfl g= NIL. For example, (GETPROP 'DEFINEQ 'ARGNAMES) = (NIL (X1 XI ... XN) . X).

SMARTARGLIST is used by BREAK (page 10.4) and ADVISE (page 10.9) with EXPLAINFL G= NIL for constructing equivalent EXPR denitions, and by the programmer's assistant command ?= (page 9.5), with EXPLAINFL G= T.

5.2 FUNCTION DEFINITION

Function de nitions are stored in a "function de nition cell" associated with each litatom. This cell is directly accessible via the two functions PUTD and GETD, but it is usually easier to de ne functions with DEFINEQ (page 5.9).

(GETD FN) [Function]

Returns the function denition of FN. Returns NIL if FN is not a litatom, or has no denition.

GETD of a compiled function constructs a pointer to the denition, with the result that two successive calls do not produce EQ results. EQP or EQUAL must be used to compare compiled denitions.

(Interlisp- 10) GETD of a SUBR performs a CONS.

(FGETD FN) [Function]

Faster version of GETD. Interpreted, generates an error, BAD ARGUMENT - FGETD, if FN is not a litatom.

FGETD is intended primarily to check whether a function *has* a de nition, rather than to obtain the de nition. Therefore, in Interlisp-10, FGETD of a SUBR returns just the address of the function de nition, not the dotted pair returned by GETD, thereby saving the CONS.

(PUTD FN DEF _) [Function]

Puts DEF into FN's function cell, and returns DEF. Generates an error, ARG NOT LITATOM, if FN is not a litatom. Generates an error, ILLEGAL ARG, if DEF is a string, number, or a litatom other than NIL.

(PUTDQ FN DEF) [NLambda Function]

Nlambda version of PUTD; both arguments are unevaluated. Returns FN.

(PUTDQ? FN DEF) [NLambda Function]

If FN is not de ned, same as PUTDQ. Otherwise, does nothing and returns NIL.

(MOVD FROM TO COPYFL G) [Function]

Moves the denition of FROM to TO, i.e., redenes TO. If COPYFL G= T, a COPY of the denition of FROM is used. COPYFL G= T is only meaningful for EXPRS, although MOVD works for compiled functions and SUBRs as well. MOVD returns

TO.

(MOVD? FROM TO COPYFL G)

[Function]

If to is not de ned, same as (MOVD from to copyfl g). Otherwise, does nothing and returns NIL.

(DEFINEQ x₁ x₂

 $x_{\rm N}$) [NLambda NoSpread Function] DEFINEQ is the function normally used for de ning functions. It takes an indenite number of arguments which are not evaluated. Each $x_{\rm i}$ must be a list de ning one function, of the form (NAME DEFINITION). For example:

```
(DEFINEQ (DOUBLE (LAMBDA (X) (IPLUS X X))) )
```

The above expression will de ne the function DOUBLE with the EXPR de nition (LAMBDA (X) (IPLUS X X)). x_i may also have the form (NAME ARGS. DEF-BOD Y), in which case an appropriate Lambda EXPR will be constructed. Therefore, the above expression is exactly the same as:

```
(DEFINEQ (DOUBLE (X) (IPLUS X X)) )
```

Note that this alternate form can only be used for Lambda functions. The rst form must be used to de ne an Nlambda function.

DEFINEQ returns a list of the names of the functions de ned.

(DEFINE x _)

[Function]

Lambda- spread version of DEFINEQ. Each element of the list x is itself a list either of the form (NAME DEFINITION) or (NAME ARGS. DEF-BODY). DEFINE will generate an error, INCORRECT DEFINING FORM, on encountering an atom where a de ning list is expected.

Note: DEFINE and DEFINEQ will operate correctly if the function is already de ned and BROKEN, ADVISED, or BROKEN-IN.

For expressions involving type-in only, if the time stamp facility is enabled (page 17.60), both DEFINE and DEFINEQ will stamp the denition with the user's initials and date.

DFNFLG [Variable]

DFNFLG is a global variable that e ects the operation of DEFINE (and DEFINEQ, which calls DEFINE). If DFNFLG= NIL, an attempt to *rede ne* a function FN will cause DEFINE to print the message (FN REDEFINED) and to save the old de nition of FN using SAVEDEF before rede ning it, except if the old and new de nitions are the same (i.e. EQUAL), the e ect is simply a no-op. If DFNFLG= T, the function is simply rede ned. If DFNFLG= PROP or ALLPROP, the new de nition is stored on the property list under the property EXPR. ALLPROP a ects the operation of RPAQQ and RPAQ (page 11.37). DFNFLG is initially NIL.

DFNFLG is reset by LOAD (page 11.4) to enable various ways of handling the de ning of functions and setting of variables when loading a le. For most applications, the user will not reset DFNFLG directly.

(SAVEDEF FN)

[Function]

Saves the de nition of FN on its property list under the property EXPR, CODE,

Function Evaluation

or SUBR depending on its FNTYP. Returns the property name used. If (GETD FN) is non-NIL, but (FNTYP FN) = NIL, SAVEDEF saves the denition on the property name LIST. This situation can arise when a function is redened which was originally dened with LAMBDA misspelled or omitted.

If FN is a list, SAVEDEF operates on each function in the list, and returns a list of the individual values.

(UNSAVEDEF FN PROP)

[Function]

Restores the denition of FN from its property list under property PR OP (see SAVEDEF above). Returns PR OP. If nothing is saved under PR OP, and FN is dened, returns (PR OP NOT FOUND), otherwise generates an error, NOT A FUNCTION.

If PROP is not given, i.e., NIL, UNSAVEDEF looks under the properties EXPR, CODE, and SUBR, in that order. The value of UNSAVEDEF is the property name, or if nothing is found and FN is a function, the value is (NOTHING FOUND); otherwise generates an error, NOT A FUNCTION.

If DFNFLG= NIL, the current denition of FN, if any, is saved using SAVEDEF. Thus one can use UNSAVEDEF to switch back and forth between two denitions of the same function, keeping one on its property list and the other in the function denition cell.

If FN is a list, UNSAVEDEF operates on each function of the list, and its value is a list of the individual values.

Both SAVEDEF and UNSAVEDEF are rede ned in more general terms (see page 11.18) to operate on typed de nitions of which a function de nition is but one example. Thus, their actual argument lists in Interlisp are di erent than given here. However, when their extra arguments are defaulted to NIL, they operate as described above.

5.3 FUNCTION EVALUATION

Usually, function application is done automatically by the Interlisp interpreter. If a form is typed into Interlisp whose CAR is a function, this function is applied to the arguments in the CDR of the form. These arguments are evaluated or not, and bound to the function parameters, as determined by the type of the function, and the body of the function is evaluated. This sequence is repeated as each form in the body of the function is evaluated.

There are some situations where it is necessary to explicitly call the evaluator, and Interlisp supplies a number of functions that will do this. These functions take "functional arguments", which may either be litatoms with function de nitions, or EXPR forms such as (LAMBDA (X)), or FUNARG expressions (see page 5.15).

The following functions are useful when one wants to supply a functional argument which will always return NIL, T, or 0.

(NILL) [NoSpread Function]

Returns NIL.

(TRUE) [NoSpread Function]

Returns T. [NoSpread Function]

Returns 0.

Note: When using EXPR expressions as functional arguments, they should be enclosed within the function FUNCTION (page 5.15) rather than QUOTE, so that they will be compiled as separate functions. FUNCTION can also be used to create FUNARG expressions, which can be used to solve some problems with referencing free variables, or to create functional arguments which carry "state" along with them.

(EVAL x _) [Function]

EVAL evaluates the expression x and returns this value, i.e., EVAL provides a way of calling the Interlisp interpreter. Note that EVAL is itself a lambda function, so *its* argument is rst evaluated, e.g.,

```
_(SETQ FOO '(ADD1 3))
(ADD1 3)
_(EVAL FOO)
4
_(EVAL 'FOO)
(ADD1 3)
```

in this case, PARENTHESIS ERROR.

Interlisp functions can either evaluate or not evaluate these arguments. For those cases where it is desirable to specify arguments unevaluated, one may use the OUOTE function:

(QUOTE x) [NLambda NoSpread Function]
This is a function that prevents its arguments from being evaluated. Its value is x itself, e.g., (QUOTE FOO) is FOO.

Note: Since giving QUOTE more than one argument is almost always a parentheses error, and one that would otherwise go undetected, QUOTE itself generates an error

(KWOTE x) [Function]

Value is an expression which when evaluated yields x. If x is NIL or a number, this is x itself. Otherwise, (LIST (QUOTE QUOTE) x). For example, if the value of x is x and the value of y is y, then (KWOTE (CONS x y)) = (QUOTE (A . B)).

(DEFEVAL TYPE FN) [Function]

Speci es how a datum of a particular type is to be evaluated. ¹ Intended primarily for user de ned data types, but works for all data types except lists, literal atoms, and numbers. Type is a type name. FN is a function object, i.e. name of a function or a lambda expression. Whenever the interpreter encounters a datum of the indicated type, FN is applied to the datum and its value returned as the result of the evaluation. Defeval returns the previous evaling function for this type. If FN = NIL, Defeval returns the current evaling function without changing it. If

¹COMPILETYPELST (page 12.9) permits the user to specify how a datum of a particular type is to be compiled.

Function Evaluation

FN = T, the evaling function is set back to the system default (which for all data types except lists is to return the datum itself).

(APPLY FN ARGLIST _)

[Function]

Applies the function FN to the arguments in the list AR GLIST, and returns its value. APPLY is a lambda function, so its arguments are evaluated, but the individual elements of AR GLIST are not evaluated. Therefore, lambda and nlambda functions are treated the same by APPLY; lambda functions take their arguments from AR GLIST without evaluating them. Note that FN may still explicitly evaluate one or more of its arguments itself, as SETQ does. Thus, (APPLY 'SETQ '(FOO (ADD1 3))) will set FOO to 4, whereas (APPLY 'SET '(FOO (ADD1 3))) will set FOO to the expression (ADD1 3).

APPLY can be used for manipulating EXPRs, for example:

```
(APPLY '(LAMBDA (X Y) (ITIMES X Y))
        ((3 4))
```

[NoSpread Function]

 $ARG_N)).$

(EVALA x A)

[Function]

Simulates a-list evaluation as in LISP 1.5. x is a form, A is a list of the form:

```
( (NAME _1 . VAL _1 ) (NAME _2 . VAL _2 ) (NAME _N . VAL _N ) )
```

The variable names and values in A are "spread" on the stack, and then x is evaluated. Therefore, any variables appearing free in x, that also appears as CAR of an element of A will be given the value in the CDR of that element.

The functions below are used to evaluate a form or apply a function repeatedly. RPT, RPTQ, and FRPTQ evaluate a given form a speci ed number of times. MAP, MAPCAR, MAPLIST, etc. apply a given function repeatedly to di erent elements of a list, possibly constructing another list. These functions allow e cient iterative computations, but they are dicult to use. For programming iterative computations, it is usually better to use the CLISP Iterative Statement facility (page 4.5), which provides a more general and complete facility for expressing iterative statements. Whenever possible, CLISP translates iterative statements into expressions using the functions below, so there is no eciency loss.

(RPT N FORM)

[Function]

Evaluates the expression FORM, N times. Returns the value of the last evaluation. 0, FORM is not evaluated, and RPT returns NIL.

Before each evaluation, the local variable RPTN is bound to the number of evaluations yet to take place. This variable can be referenced within FORM. For example, (RPT 10 '(PRINT RPTN)) will print the numbers 10, 9, 1, and return 1.

(RPTQ n form $_1$ form $_2$ form $_N$)

[NLambda NoSpread Function]

Nlambda- nospread version of RPT: N is evaluated, FORM i are not. Returns the value of the last evaluation of FORM $_{\rm N}$.

(MAP MAPX MAPFN1 MAPFN2)

[Function]

If Mapfn2 is NIL, MAP applies the function Mapfn1 to successive tails of the list Mapx . That is, rst it computes (Mapfn1 Mapx), and then (Mapfn1 (CDR Mapx)), etc., until Mapx becomes a non-list. If Mapfn2 is provided, (Mapfn2 Mapx) is used instead of (CDR Mapx) for the next call for Mapfn1 , e.g., if Mapfn2 were CDDR, alternate elements of the list would be skipped. MAP returns NIL.

(MAPC MAPX MAPFN1 MAPFN2)

[Function]

Identical to MAP, except that (MAPFN1 (CAR MAPX)) is computed at each iteration instead of (MAPFN1 MAPX), i.e., MAPC works on elements, MAP on tails. MAPC returns NIL.

(MAPLIST MAPX MAPFN1 MAPFN2)

[Function]

Successively computes the same values that MAP would compute, and returns a list consisting of those values.

(MAPCAR MAPX MAPFN1 MAPFN2)

[Function]

Computes the same values that MAPC would compute, and returns a list consisting of those values, e.g., (MAPCAR X 'FNTYP) is a list of FNTYPs for each element on X.

(MAPCON MAPX MAPFN1 MAPFN2)

[Function]

Computes the same values as MAP and MAPLIST but NCONCs these values to form a list which it returns.

(MAPCONC MAPX MAPFN1 MAPFN2)

[Function]

Computes the same values as MAPC and MAPCAR, but NCONCs the values to form a list which it returns.

Note that MAPCAR creates a new list which is a mapping of the old list in that each element of the new list is the result of applying a function to the corresponding element on the original list. MAPCONC is used when there are a *variable* number of elements (including none) to be inserted at each iteration. Examples:

This MAPCONC returns a list consisting of MAPX with all NILs removed.

This MAPCONC returns a linear list consisting of all the lists on MAPX.

Since MAPCONC uses NCONC to string the corresponding lists together, in this example the original list will be altered to be ((A B D E F G) C (D E F G) (G) H I). If this is an undesirable side e ect, the functional argument to MAPCONC should return instead a top level copy of the lists, i.e. (LAMBDA (Y) (if (LISTP Y) then (APPEND Y) else NIL))).

Function Evaluation

(MAP2C MAPX MAPY MAPFN1 MAPFN2) [Function] Identical to MAPC except MAPFN1 is a function of two arguments, and (MAPFN1 (CAR MAPX) (CAR MAPY)) is computed at each iteration. Terminates when either MAPX or MAPY is a non-list. MAPFN2 is still a function of one argument, and is applied twice on each iteration; (MAPFN2 MAPX) gives the new MAPX , (MAPFN2 MAPY) the new MAPY . CDR is used if MAPFN2 is not supplied, i.e., is NIL. MAPY MAPFN1 MAPFN2) [Function] (MAP2CAR MAPX Identical to MAPCAR except MAPFN1 is a function of two arguments and (MAPFN1 (CAR MAPX) (CAR MAPY)) is used to assemble the new list. Terminates when either MAPX or MAPY is a non-list. (SUBSET MAPX MAPFN1 MAPFN2) [Function] Applies MAPFN1 to elements of MAPX and returns a list of those elements for which this application is non-NIL, e.g., (SUBSET '(A B 3 C 4) 'NUMBERP) = (3 4).plays the same role as with MAP, MAPC, et al. (EVERY EVER YX EVER YFN1 EVER YFN2) [Function] Returns T if the result of applying EVER YFN1 to each element in EVER YX is true, otherwise NIL. For example, (EVERY '(X Y Z) 'ATOM) EVERY operates by evaluating (EVER YFN1 (CAR EVER YX) EVER YX). second argument is passed to EVER YFN1 so that it can look at the next element on EVER YX if necessary. If EVER YFN1 yields NIL, EVERY immediately returns NIL. Otherwise, EVERY computes (EVER YFN2 EVER YX), or (CDR EVER YX) if EVER YFN2 = NIL, and uses this as the "new" EVER YX, and the process continues. For example, (EVERY x 'ATOM 'CDDR) is true if every other element of x is atomic. (SOME SOMEX SOMEFN1 SOMEFN2) [Function] Returns the tail of SOMEX beginning with the rst element that satisfes SOMEFN1, i.e., for which SOMEFN1 applied to that element is true. Value is NIL if no such element exists. (SOME X '(LAMBDA (Z) (EQUAL Z Y))) is equivalent to (MEMBER Y X). SOME operates analogously to EVERY. At each stage, (SOMEFN1 (CAR SOMEX) SOMEX) is computed, and if this is not NIL, SOMEX is returned as the value of SOME. Otherwise, (SOMEFN2 SOMEX) is computed, or (CDR SOMEX) if somefine = NIL, and used for the next somex. (NOTANY SOMEX SOMEFN2) [Function] SOMEFN1 (NOT (SOME SOMEX SOMEFN1 SOMEFN2))

(NOTEVERY EVER YX EVER YFN1 EVER YFN2)

(NOT (EVERY EVER YX EVER YFN1 EVER YFN2))

(MAPRINT LST FILE LEFT RIGHT SEP PFN LISPXPRINTFL G)

A general printing function. It cycles through LST applying PFN (or PRIN1 if PFN not given) to each element of LST. Between each application, MAPRINT performs

PRIN1 of SEP (or "if SEP = NIL). If LEFT is given, it is printed (using PRIN1) initially; if RIGHT is given it is printed (using PRIN1) at the end.

For example, (MAPRINT X NIL '%('%)) is equivalent to PRIN1 for lists. To print a list with commas between each element and a nal "." one could use (MAPRINT X T NIL '%. '%,).

If LISPXPRINTFL G= T, LISPXPRIN1 (page 8.20) is used instead of PRIN1.

5.4 FUNCTIONAL ARGUMENTS

When using functional arguments, the following function is very useful:

```
(FUNCTION FN ENV) [NLambda Function]
```

If ENV = NIL, FUNCTION is the same as QUOTE, except that it is treated dierently when compiled. Consider the function de nition:

```
(DEFINEQ (FOO (FIE LST (FUNCTION (LAMBDA (Z) (ITIMES Z Z)))))
```

FOO calls the function FIE with the value of LST and the EXPR expression (LAMBDA (Z) (LIST (CAR Z))).

If FOO is run interpreted, it doesn't make any di erence whether FUNCTION or QUOTE is used. However, when FOO is compiled, if FUNCTION is used the compiler will de ne and compile the EXPR as an auxiliary function (See page 12.8). The compiled EXPR will run considerably faster, which can make a big di erence if it is applied repeatedly.

Note: Compiling FUNCTION will *not* create an auxiliary function if it is a functional argument to a function that compiles open, such as most of the mapping functions (MAPCAR, MAPLIST, etc.).

If ENV is not NIL, it can be a list of variables that are (presumably) used freely by FN. In this case, the value of FUNCTION is an expression of the form (FUNARG FN POS), where POS is a stack pointer to a frame that contains the variable bindings for those variables on ENV. ENV can also be a stack pointer itself, in which case the value of FUNCTION is (FUNARG FN ENV). Finally, ENV can be an atom, in which case it is evaluated, and the value interpreted as described above.

As explained above, one of the possible values that FUNCTION can return is the form (FUNARG FN POS), where FN is a function and POS is a stack pointer. FUNARG is not a function itself. Like LAMBDA and NLAMBDA, it has meaning and is specially recognized by Interlisp only in the context of applying a function to arguments. In other words, the expression (FUNARG FN POS) is used exactly like a function. When a FUNARG expression is applied or is CAR of a form being EVAL'ed, the APPLY or EVAL takes place in the access environment specied by ENV (see page 7.1). Consider the following example:

```
_ (DEFINEQ (DO.TWICE (FN VAL)
```

Functional Arguments

```
(APPLY* FN (APPLY* FN VAL))))

(DO.TWICE)

(DO.TWICE [FUNCTION (LAMBDA (X) (IPLUS X X))]

5)

20

(SETQ VAL 1)

(DO.TWICE [FUNCTION (LAMBDA (X) (IPLUS X VAL))]

5)

20

(DO.TWICE [FUNCTION (LAMBDA (X) (IPLUS X VAL)) (VAL)]

5)

7
```

DO.TWICE is defined to apply a function FN to a value VAL, and apply FN again to the value returned; in other words it calculates (FN (FN VAL)). Given the EXPR expression (LAMBDA (X) (IPLUS X X)), which doubles a given value, it correctly calculates (FN (FN 5)) = (FN 10) = 20. However, when given (LAMBDA (X) (IPLUS X VAL)), which should add the value of the global variable VAL to the argument X, it does something unexpected, returning 20 again, rather than 5+1+1 = 7. The problem is that when the EXPR is evaluated, it is evaluated in the context of DO.TWICE, where VAL is bound to the second argument of DO.TWICE, namely 5. In this case, one solution is to use the ENV argument to FUNCTION to construct a FUNARG expression which contains the value of VAL at the time that the FUNCTION is executed. Now, when (LAMBDA (X) (IPLUS X VAL)) is evaluated, it is evaluated in an environment where the global value of VAL is accessable. Admittedly, this is a somewhat contrived example (it would be easy enough to change the argument names to DO.TWICE so there would be no con ict), but this situation arises occasionally with large systems of programs that construct functions, and pass them around.

Note: System functions with functional arguments (APPLY, MAPCAR, etc.) are compiled so that their arguments are local, and not accessable (see page 12.4). This reduces problems with con icts with free variables used in functional arguments.

FUNARG expressions can be used for more than just circumventing the clashing of variables. For example, a FUNARG expression can be returned as the value of a computation, and then used "higher up". Furthermore, if the function in a FUNARG expression *sets* any of the variables contained in the frame, only the frame would be changed. For example, consider the following function:

The function MAKECOUNTER returns a FUNARG that increments and returns the previous value of the counter CNT. However, this is done within the environment of the call to MAKECOUNTER where FUNCTION was executed, which the FUNARG expression "carries around" with it, even after MAKECOUNTER has nished executing. Note that each call to MAKECOUNTER creates a FUNARG expression with a new, independent environment, so that multiple counters can be generated and used:

```
_ (SETQ C1 (MAKECOUNTER 1))
(FUNARG (LAMBDA NIL (PROG1 CNT (SETQ CNT (ADD1 CNT)))) #1,13724/*FUNARG)
_ (APPLY C1)
1
```

```
_ (APPLY C1)
2
_ (SETQ C2 (MAKECOUNTER 17))
(FUNARG (LAMBDA NIL (PROG1 CNT (SETQ CNT (ADD1 CNT)))) #1,13736/*FUNARG)
_ (APPLY C2)
17
_ (APPLY C2)
18
_ (APPLY C1)
3
_ (APPLY C2)
19
```

By creating a FUNARG expression with FUNCTION, a program can create a function object which has updateable binding(s) associated with the object which last *between* calls to it, but are only accessible through that instance of the function. For example, using the FUNARG device, a program could maintain two di erent instances of the same random number generator in di erent states, and run them independently.

Note: In Interlisp- 10, environment switching is expensive because it is a shallow-binding system (see page 7.1), so this may restrict the applications of FUNARG expressions.

5.5 MACROS

Macros provide an alternative way of specifying the action of a function. Whereas function de nitions are evaluated with a "function call", which involves binding variables and other housekeeping tasks, macros are evaluated by *translating* one Interlisp form into another, which is then evaluated.

A litatom may have both a function de nition and a macro de nition. When a form is evaluated by the interpreter, if the CAR has a function de nition, it is used (with a function call), otherwise if it has a macro de nition, then that is used. However, when a form is compiled, the CAR is checked for a macro de nition rst, and only if there isn't one is the function de nition compiled. This allows functions that behave di erently when compiled and interpreted. For example, it is possible to de ne a function that, when interpreted, has a function de nition that is slow and has a lot of error checks, for use when debugging a system. This function could also have a macro de nition that de nes a fast version of the function, which is used when the debugged system is compiled.

Macro denitions are represented by lists that are stored on the property list of a litatom. Macros are often used for functions that should be compiled dierently in dierent. Interlisp implementations, and the exact property name a macro denition is stored under determines whether it should be used in a particular implementation. The global variable MACROPROPS contains a list of all possible macro property names which should be saved by the MACROS le package command. Typical macro property names are 10MACRO for Interlisp-10, DMACRO for Interlisp-D,2 and MACRO for 'implementation independent' macros. The global variable COMPILERMACROPROPS is a list of macro property names. Interlisp determines whether a litatom has a macro denition by checking these property names, in order, and

²also VAXMACRO for Interlisp- VAX, and JMACRO for Interlisp- Jerico.

Macros

using the rst non-NIL property value as the macro de nition. In Interlisp- D this list contains DMACRO and MACRO in that order so that DMACROs will override the implementation- independent MACRO properties. In general, use a DMACRO property for macros that are to be used only in Interlisp- D, use 10MACRO for macros that are to be used only in Interlisp- 10, and use MACRO for macros that are to a ect both systems.

Macro de nitions can take the following forms:

```
(LAMBDA ) or (NLAMBDA
```

A function can be made to compile open by giving it a macro denition of the form (LAMBDA) or (NLAMBDA), e.g., (LAMBDA (X) (COND ((GREATERP X 0) X) (T (MINUS X)))) for ABS. The e ect is as if the macro denition were written in place of the function wherever it appears in a function being compiled, i.e., it compiles as a lambda or nlambda expression. This saves the time necessary to call the function at the price of more compiled code generated in-line.

```
(NIL EXPRESSION ) or (LIST EXPRESSION )
```

"Substitution" macro. Each argument in the form being evaluated or compiled is substituted for the corresponding atom in LIST, and the result of the substitution is used instead of the form. For example, if the macro de nition of ADD1 is ((X) (IPLUS X 1)), then, (ADD1 (CAR Y)) is compiled as (IPLUS (CAR Y) 1).

Note that ABS could be defined by the substitution macro ((X) (COND ((GREATERP X 0) X) (T (MINUS X)))). In this case, however, (ABS (FOO X)) would compile as

and (FOO X) would be evaluated two times. (Code to evaluate (FOO X) would be generated three times.)

```
(OPENLAMBDA AR GS BOD Y)
```

This is a cross between substitution and LAMBDA macros. When the compiler processes an OPENLAMBDA, it attempts to substitute the actual arguments for the formals wherever this preserves the frequency and order of evaluation that would have resulted from a LAMBDA expression, and produces a LAMBDA binding only for those that require it.

Т

When a macro de nition is the atom T, it means that the compiler should ignore the macro, and compile the function de nition; this is a simple way of turning o other macros. For example, the user may have a function that runs in both Interlisp- D and Interlisp- 10, but has a macro de nition that should only be used when compiling in Interlisp- 10. If the MACRO property has the macro speci cation, a DMACRO of T will cause it to be ignored by the Interlisp- D compiler. Note that this DMACRO would not be necessary if the macro were specified by a 10MACRO instead of a MACRO.

```
(= . OTHER- FUNCTION )
```

A simple way to tell the compiler to compile one function exactly as it would compile another. For example, when compiling in Interlisp- D, FRPLACAs are treated as RPLACAs. This is achieved by having FRPLACA have a DMACRO of (= . RPLACA).

```
(LITATOM EXPRESSION )
```

If a macro de nition begins with a litatom other than those given above, this allows *computation* of the Interlisp expression to be evaluated or compiled in place of the form. LITATOM is bound to the CDR of the calling form, EXPRESSION is evaluated, and the result of this evaluation is evaluated or compiled in place of the form. For example, LIST could be compiled using the computed macro:

```
[X (LIST 'CONS (CAR X) (AND (CDR X) (CONS 'LIST (CDR X]
```

This would cause (LIST X Y Z) to compile as (CONS X (CONS Y (CONS Z NIL))). Note the recursion in the macro expansion.

If the result of the evaluation is the litatom IGNOREMACRO, the macro is ignored and the compilation of the expression proceeds as if there were no macro de nition. If the litatom in question is normally treated specially by the compiler (CAR, CDR, COND, AND, etc.), and also has a macro, if the macro expansion returns IGNOREMACRO, the litatom will still be treated specially.

In Interlisp-10, if the result of the evaluation is the atom INSTRUCTIONS, no code will be generated by the compiler. It is then assumed the evaluation was done for e ect and the necessary code, if any, has been added. This is a way of giving direct instructions to the compiler if you understand it.

Note: It is often useful, when constructing complex macro expressions, to use the BQUOTE facility (see page 6.39).

The following function is quite useful for debugging macro de nitions:

```
(EXPANDMACRO FORM QUIETFL G _ )
```

Takes a form whose CAR has a macro de nition and expands the form as it would be compiled. The result is prettyprinted, unless QUIETFL G= T, in which case the result is simply returned.

[Function]

5.5.1 MACROTRAN

Interpreted macros are implemented by the function MACROTRAN. When the interpreter encounters a form CAR of which is an unde ned function, ³ MACROTRAN is called. If CAR of the form has a macro de nition, the macro is expanded, and the result of this expansion is evaluated in place of the original form. CLISPTRAN (page 16.19) is used to save the result of this expansion so that the expansion only has to be done once. On subsequent occasions, the translation (expansion) is retrieved from CLISPARRAY the same as for other CLISP constructs; MACROTRAN never even has to be invoked.

Sometimes, macros contain calls to functions that assume that the macro is being compiled. The variable SHOULDCOMPILEMACROATOMS is a list of functions that should be compiled to work correctly (initially (OPCODES) in Interlisp- D, (ASSEMBLE LOC) in Interlisp- 10). UNSAFEMACROATOMS is a list

³In other words, if you have a macro on FOO, then typing (FOO 'A 'B) will work, but FOO(A B) will not work.

MACROTRAN

of functions which e ect the operation of the compiler, so such macro forms shouldn't even be expanded except by the compiler (initially NIL in Interlisp- D, (C2EXP STORIN CEXP COMP) in Interlisp- 10). If MACROTRAN encounters a macro containing calls to functions on these two lists, instead of the macro being expanded, a dummy function is created with the form as its de nition, and the dummy function is then compiled. A form consisting of a call to this dummy function with no arguments is then evaluated in place of the original form, and CLISPTRAN is used to save the translation as described above. There are some situations for which this procedure is not amenable, e.g. a GO inside the form which is being compiled will cause the compiler to give an UNDEFINED TAG error message because it is not compiling the entire function, just a part of it.

Note: MACROTRAN is an entry on DWIMUSERFORMS (page 15.10) and thus will not work if DWIM is not enabled.
