

CHAPTER 11

FILE PACKAGE

Most implementations of Lisp treat symbolic les as unstructured text, much as they are treated in most conventional programming environments. Function definitions are edited with a character-oriented text editor, and then the changed definitions (or sometimes the entire le) is read or compiled to install those changes in the running memory image. Interlisp incorporates a different philosophy. A symbolic le is considered as a database of information about a group of data objects: function definitions, variable values, record declarations, etc. The text in a symbolic le is never edited directly. Definitions are edited only after their textual representations on les have been converted to data-structures that reside inside the Lisp address space. The programs for editing definitions inside Interlisp can therefore make use of the full set of data-manipulation capabilities that the environment already provides, and editing operations can be easily intermixed with the processes of evaluation and compilation.

Interlisp is thus a ‘resident’ programming environment, and as such it provides facilities for moving definitions back and forth between memory and the external databases on symbolic les, and for doing the bookkeeping involved when definitions on many symbolic les with compiled counterparts are being manipulated. The le package provides those capabilities. It removes from the user the burden of keeping track of where things are and what things have changed. The le package also keeps track of which les have been modified and need to be updated and recompiled.

The le package is integrated into many other system packages. For example, if only the compiled version of a le is loaded and the user attempts to edit a function, the le package will attempt to load the source of that function from the appropriate symbolic le. In many cases, if a datum is needed by some program, the le package will automatically retrieve it from a le if it is not already in the user’s working environment.

Some of the operations of the le package are rather complex. For example, the same function may appear in several different les, or the symbolic or compiled les may be in different directories, etc. Therefore, this chapter does not document how the le package works in each and every situation, but instead makes the deliberately vague statement that it does the ‘right’ thing with respect to keeping track of what has been changed, and what le operations need to be performed in accordance with those changes.

For a simple illustration of what the le package does, suppose that the symbolic le FOO contains the functions FOO1 and FOO2, and that the le BAR contains the functions BAR1 and BAR2. These two les could be loaded into the environment with the function LOAD:

```
-- (LOAD 'FOO)
FILE CREATED 4-MAR-83 09:26:55
FOOCOMS
{DSK}FOO.;1
-- (LOAD 'BAR)
FILE CREATED 4-MAR-83 09:27:24
BARCOMS
{DSK}BAR.;1
```

Now, suppose that we change the definition of FOO2 with the editor, and we define two new functions, NEW1 and NEW2. At that point, the le package knows that the in-memory definition of FOO2 is no longer consistent with the definition in the le FOO, and that the new functions have been defined but have not yet been associated with a symbolic le and saved on permanent storage. The function FILES? summarizes this state of affairs and enters into an interactive dialog in which we can specify what les the new functions are to belong to.

```
_ (FILES?)
FOO...to be dumped.
  plus the functions: NEW1,NEW2
want to say where the above go ? Yes
(functions)
NEW1  File name: BAR
NEW2  File name: ZAP
      new file ? Yes
NIL
```

The le package knows that the le FOO has been changed, and needs to be dumped back to permanent storage. This can be done with MAKEFILE.

```
_(MAKEFILE 'FOO)
{DSK}FOO.;2
```

Since we added NEW1 to the old le BAR and established a new le ZAP to contain NEW2, both BAR and ZAP now also need to be dumped. This is confirmed by a second call to FILES?:

```
_ (FILES?)
BAR, ZAP...to be dumped.
FOO...to be listed.
FOO...to be compiled
NIL
```

We are also informed that the new version we made of FOO needs to be listed (sent to a printer) and that the functions on the le must be compiled.

Rather than doing several MAKEFILEs to dump the les BAR and ZAP, we can simply call CLEANUP. Without any further user interaction, this will dump any les whose definitions have been modified. CLEANUP will also send any unlisted les to the printer and recompile any les which need to be recompiled. CLEANUP is a useful function to use at the end of a debugging session. It will call FILES? if any new objects have been defined, so the user does not lose the opportunity to say explicitly where those belong. In effect, the function CLEANUP executes all the operations necessary to make the user's permanent les consistent with the definitions in his current core-image.

```
_ (CLEANUP)
FOO...compiling {DSK}FOO.;2
.
.
.
BAR...compiling {DSK}BAR.;2
.
.
.
```

FILE PACKAGE

```
ZAP...compiling {DSK}ZAP.;1
.
.
.
```

In addition to the definitions of functions, symbolic lisp files in Interlisp can contain definitions of a variety of other types, e.g. variable values, property lists, record declarations, macro definitions, hash arrays, etc. In order to treat such a diverse assortment of data uniformly from the standpoint of lisp operations, the lisp package uses the concept of a *typed definition*, of which a function definition is just one example. A typed definition associates with a name (usually a lisp atom), a definition of a given type (called the lisp package type). Note that the same name may have several definitions of different types. For example, a lisp atom may have both a function definition and a variable definition. The lisp package also keeps track of the files that a particular typed definition is stored on, so one can think of a typed definition as a relation between four elements: a name, a definition, a type, and a file.

Symbolic files on permanent storage devices are referred to by names that obey the naming conventions of those devices, usually including host, directory, and version fields. When such definition groups are noticed by the lisp package, they are assigned simple *root names* and these are used by all lisp package operations to refer to those groups of definitions. The root name for a group is computed from its full permanent storage name by applying the function `ROOTFILENAME`; this strips off the host, directory, version, etc., and returns just the simple name field of the file. For each file, the lisp package also has a data structure that describes what definitions it contains. This is known as the *commands* of the file, or its “*lecoms*”. By convention, the *lecoms* of a file whose root name is *x* is stored as the value of the lisp atom `xCOMS`. For example, the value of `FOOCOMS` is the *lecoms* for the file `FOO`. This variable can be directly manipulated, but the lisp package contains facilities such as `FILES?` which make constructing and updating *lecoms* easier, and in some cases automatic. See page 11.32.

The lisp package is able to maintain its databases of information because it is notified by various other routines in the system when events take place that may change that database. A file is “noticed” when it is loaded, or when a new file is stored (though there are ways to explicitly notice files without completely loading all their definitions). Once a file is noticed, the lisp package takes it into account when modifying *lecoms*, dumping files, etc. The lisp package also needs to know what typed definitions have been changed or what new definitions have been introduced, so it can determine which files need to be updated. This is done by “marking changes”. All the system functions that perform lisp package operations (`LOAD`, `TCOMPL`, `PRETTYDEF`, etc.), as well as those functions that define or change data, (`EDITF`, `EDITV`, `EDITP`, `DWIM` corrections to user functions) interact with the lisp package. Also, *typed-in* assignment of variables or property values is noticed by the lisp package. (Note that modifications to variable or property values during the execution of a function body are not noticed.) In some cases the marking procedure can be subtle, e.g. if the user edits a property list using `EDITP`, only those properties whose values are actually changed (or added) are marked.

All lisp package operations can be disabled with `FILEPKGFLG`.

`FILEPKGFLG`

[Variable]

The lisp package can be disabled by setting `FILEPKGFLG` to `NIL`. This will turn off noticing files and marking changes. `FILEPKGFLG` is initially `T`.

The rest of this chapter goes into further detail about the lisp package. Functions for loading and storing symbolic files are presented first, followed by functions for adding and removing typed definitions from files, moving typed definitions from one file to another, determining which file a particular definition is stored in, and so on.

Loading Files

11.1 LOADING FILES

The functions below load information from symbolic les into the Interlisp environment. A symbolic le contains a sequence of Interlisp expressions that can be evaluated to establish specified typed definitions. The expressions on symbolic les are read using `FILERDTBL` as the readtable.

The loading functions all have an argument `LDFLG`. `LDFLG` affects the operation of `DEFINE`, `DEFINEQ`, `RPAQ`, `RPAQ?`, and `RPAQQ`. While a source le is being loaded, `DFNFLG` (page 5.9) is rebound to `LDFLG`. Thus, if `LDFLG = NIL`, and a function is redefined, a message is printed and the old definition saved. If `LDFLG = T`, the old definition is simply overwritten. If `LDFLG = PROP`, the functions are stored as “saved” definitions on the property lists under the property `EXPR` instead of being installed as the active definitions. If `LDFLG = ALLPROP`, not only function definitions but also variables set by `RPAQQ`, `RPAQ`, `RPAQ?` are stored on property lists (except when the variable has the value `NOBIND`, in which case they are set to the indicated value regardless of `DFNFLG`).

Another option is available for users who are loading systems for others to use and who wish to suppress the saving of information used to aid in development and debugging. If `LDFLG = SYSLOAD`, `LOAD` will: (1) Rebind `DFNFLG` to `T`, so old definitions are simply overwritten; (2) Rebind `LISPXHIST` to `NIL`, thereby making the `LOAD` not be undoable and eliminating the cost of saving undo information (See page 8.22); (3) Rebind `ADDSPELLFLG` to `NIL`, to suppress adding to spelling lists; (4) Rebind `FILEPKGFLG` to `NIL`, to prevent the le from being “noticed” by the le package; (5) Rebind `BUILDMAPFLG` to `NIL`, to prevent a le map from being constructed; (6) After the load has completed, set the `lecoms` variable and any `levars` variables¹ to `NOBIND`; and (7) Add the le name to `SYSFILES` rather than `FILELST`.

Note: All functions that have `LDFLG` as an argument perform spelling correction using `LOADOPTIONS` as a spelling list when `LDFLG` is not a member of `LOADOPTIONS`. `LOADOPTIONS` is initially `(NIL T PROP ALLPROP SYSLOAD)`.

`(LOAD FILE LDFLG PRINTFLG)` [Function]
Reads successive expressions from `FILE` (with `FILERDTBL` as readtable) and evaluates each as it is read, until it reads either `NIL`, or the single atom `STOP`. Note that `LOAD` can be used to load both symbolic and compiled les. Returns `FILE` (full name).

If `PRINTFLG = T`, `LOAD` prints the value of each expression; otherwise it does not.

`(LOAD? FILE LDFLG PRINTFLG)` [Function]
Similar to `LOAD` except that it does not load `FILE` if it has already been loaded, in which case it returns `NIL`.

Note: The test is whether the root name of `FILE` has a `FILEDATES` property (page 11.13).

¹A `levars` variable is any variable appearing in a le package command of the form `(FILECOM * VARIABLE)` (see page 11.30). Therefore, if the `lecoms` includes `(FNS * FOOFNS)`, `FOOFNS` is set to `NOBIND`. If the user wants the value of such a variable to be retained, even when the le is loaded with `LDFLG = SYSLOAD`, then he should replace the variable with an equivalent, *non-atomic* expression, such as `(FNS * (PROGN FOOFNS))`.

FILE PACKAGE

(LOADFNS FNS FILE LDFLG VARS)

[Function]

Permits selective loading of definitions. FNS is a list of function names, a single function name, or T, meaning to load all of the functions on the le. FILE can be either a compiled or symbolic le. If a compiled definition is loaded, so are all compiler-generated subfunctions. The interpretation of LDFLG is the same as for LOAD.

If FILE= NIL, LOADFNS will use WHEREIS (page 11.10) to determine where the first function in FNS resides, and load from that le. Note that the le must previously have been “noticed” (see page 11.12). If WHEREIS returns NIL, and the WHEREIS package (page 23.40) has been loaded, LOADFNS will use the WHEREIS data base to find the le containing FN.

VARS specifies which non-DEFINEQ expressions are to be loaded (i.e., evaluated): T means all, NIL means none, VARS means to evaluate all variable assignment expressions (beginning with RPAQ, RPAQQ, or RPAQ?, see page 11.37), and any other atom is the same as specifying a list containing that atom.

If VARS is a list, each element in VARS is “matched” against each non-DEFINEQ expression, and if any elements in VARS “match” successfully, the expression is evaluated. “Matching” is defined as follows: If an element of VARS is an atom, it matches an expression if it is EQ to either the CAR or the CADR of the expression. If an element of VARS is a list, it is treated as an edit pattern (page 17.13), and matched with the entire expression (using EDIT4E, page 17.57). For example, if VARS was (FOOCOMS DECLARE: (DEFLIST & (QUOTE MACRO))), this would cause (RPAQQ FOOCOMS), all DECLARE:s, and all DEFLISTs which set up MACROS to be read and evaluated.

If VARS is a list and (FNTYP VARS) is true (VARS is a function definition), then LOADFNS will invoke that function on every non-DEFINEQ expression being considered, applying it to two arguments, the first and second elements in the expression. If the function returns NIL, the expression will be skipped; if it returns a non-NIL litatom (e.g. T), the expression will be evaluated; and if it returns a list, this list is evaluated instead of the expression. Note: The le pointer is set to the very beginning of the expression before calling the VARS function definition, so it may read the entire expression if necessary. If the function returns a litatom, the le pointer is reset and the expression is READ or SKREAD. However, the le pointer is not reset when the function returns a list, so the function must leave it set immediately after the expression that it has presumably read.

LOADFNS returns a list of: (1) The names of the functions that were found; (2) A list of those functions not found (if any) headed by the litatom NOT-FOUND:; (3) All of the expressions that were evaluated; (4) A list of those members of VARS for which no corresponding expressions were found (if any), again headed by the litatom NOT-FOUND:. For example,

```
_ (LOADFNS '(FOO FIE FUM) FILE NIL '(BAZ (DEFLIST &)))  
(FOO FIE (NOT-FOUND: FUM) (RPAQ BAZ ) (NOT-FOUND: (DEFLIST  
&)))
```

(LOADVARS VARS FILE LDFLG)

[Function]

Same as (LOADFNS NIL FILE LDFLG VARS).

Storing Files

(LOADFROM FILE FNS LDFLG) [Function]
Same as (LOADFNS FNS FILE LDFLG T).

Once the `le` package has noticed a `le`, the user can edit functions contained in the `le` without explicitly loading them. Similarly, those functions which have not been modified do not have to be loaded in order to write out an updated version of the `le`. Files are normally noticed (i.e., their contents become known to the `le` package; see page 11.12) when either the symbolic or compiled versions of the `le` are loaded. If the `le` is *not* going to be loaded completely, the preferred way to notice it is with `LOADFROM`. Note that the user can also load some functions at the same time by giving `LOADFROM` a second argument, but it is normally used simply to inform the `le` package about the existence and contents of a particular `le`.

(LOADBLOCK FN FILE LDFLG) [Function]
Calls `LOADFNS` on those functions contained in the block declaration containing `FN` (See page 12.14). `LOADBLOCK` is designed primarily for use with symbolic `les`, to load the `EXPRS` for a given block. It will not load a function which already has an in-core `EXPR` definition, and it will not load the block name, unless it is also one of the block functions.

(LOADCOMP FILE LDFLG) [Function]
Performs all operations on `FILE` associated with compilation, i.e. evaluates all expressions under a `DECLARE: EVAL@COMPILE` (see page 11.26), and “notices” the function and variable names by adding them to the lists `NOFIXFNSLST` and `NOFIXVARSLST` (see page 16.16).

Thus, if building a system composed of many `les` with compilation information scattered among them, all that is required to compile one `le` is to `LOADCOMP` the others.

(LOADCOMP? FILE LDFLG) [Function]
Similar to `LOADCOMP`, except it does not load if `le` has already been loaded, in which case its value is `NIL`.

11.2 STORING FILES

(MAKEFILE FILE OPTIONS REPRINTFNS SOURCEFILE) [Function]
Makes a new version of the `le` `FILE`, storing the information specified by `FILE`'s `le`coms. Notices `FILE` if not previously noticed (see page 11.12). Then, it adds `FILE` to `NOTLISTEDFILES`² and `NOTCOMPILEDFILES`.³

`OPTIONS` is a listatom or list of listatoms which specify options. By specifying certain options, `MAKEFILE` can automatically compile or list `FILE`. Note that if `FILE` does not contain any function definitions, it is not compiled even when `OPTIONS` specifies

²Except if `FILE` has on its property list the property `FILETYPE` with value `DON'TLIST`, or a list containing `DON'TLIST`.

³Except if `FILE` has on its property list the property `FILETYPE` with value `DON'TCOMPILE`, or a list containing `DON'TCOMPILE`. Also, if `FILE` does not contain any function definitions, it is not added to `NOTCOMPILEDFILES`, and it is not compiled even when `OPTIONS` specifies `C` or `RC`.

FILE PACKAGE

C or RC. The options are spelling corrected using the list MAKEFILEOPTIONS. If spelling correction fails, MAKEFILE generates an error. The options are interpreted as follows:

C	
RC	After making FILE, MAKEFILE will compile FILE by calling TCOMPL (if C is specified) or RECOMPILE (if RC is specified). If there are any block declarations specified in the lecoms for FILE, BCOMPL or BRECOMPILE will be called instead.
	If F, ST, STF, or S is the <i>next</i> item on OPTIONS following C or RC, it is given to the compiler as the answer to the compiler's question LISTING? (see page 12.1). For example, (MAKEFILE 'FOO' (C F LIST)) will dump FOO, then TCOMPL or BCOMPL it specifying that functions are not to be redefined, and finally list the le.
LIST	After making FILE, MAKEFILE calls LISTFILES to print a hardcopy listing of FILE.
CLISPIFY	MAKEFILE calls PRETTYDEF with CLISPIFYPRETTYFLG= T (see page 16.20). This causes CLISPIFY to be called on each function defined as an EXPR before it is prettyprinted. ⁴
NOCLISP	MAKEFILE calls PRETTYDEF with PRETTYTRANFLG= T (see page 16.20). This causes CLISP translations to be printed, if any, in place of the corresponding CLISP expressions, e.g., iterative statements, record expressions, PRINTOUT forms, etc.
FAST	MAKEFILE calls PRETTYDEF with PRETTYFLG= NIL (see page 6.54). This causes data objects to be printed rather than prettyprinted, which is much faster.
REMAKE	MAKEFILE "remakes" FILE: The prettyprinted definitions of functions that have not changed are copied from an earlier version of the symbolic le. Only those functions that have changed are prettyprinted. See page 11.10.
NEW	MAKEFILE does <i>not</i> remake FILE. If MAKEFILEREMAKEFLG= T (the initial setting), the default for all calls to MAKEFILE is to remake. The NEW option can be used to override this default.
REPRINTFNS	and SOURCEFILE are used when remaking a le, as described on page 11.10.

⁴Alternatively, if FILE has the property FILETYPE with value CLISP or a list containing CLISP, PRETTYDEF is called with CLISPIFYPRETTYFLG reset to CHANGES, which will cause CLISPIFY to be called on all functions marked as having been changed. If FILE has property FILETYPE with value CLISP, the compiler will DWIMIFY its functions before compiling them (see page 12.9).

Storing Files

If a remake is *not* being performed, MAKEFILE checks the state of FILE to make sure that the entire source file was actually LOADED. If FILE was loaded as a compiled file, MAKEFILE prints the message CAN'T DUMP: ONLY THE COMPILED FILE HAS BEEN LOADED. Similarly, if only some of the symbolic definitions were loaded via LOADFNS or LOADFROM, MAKEFILE prints CAN'T DUMP: ONLY SOME OF ITS SYMBOLICS HAVE BEEN LOADED. In both cases, MAKEFILE will then ask the user if it should dump anyway; if the user declines, MAKEFILE does not call PRETTYDEF, but simply returns (FILE NOT DUMPED) as its value.

The user can indicate that FILE must be block compiled together with other files as a unit by putting a list of those files on the property list of each file under the property FILEGROUP. If FILE has a FILEGROUP property, the compiler will not be called until all files on this property have been dumped that need to be.

MAKEFILE operates by rebinding PRETTYFLG, PRETTYTRANFLG, and CLISPIFYPRETTYFLG, evaluating each expression on MAKEFILEFORMS (under errorset protection), and then calling PRETTYDEF. The user can add expressions to MAKEFILEFORMS to implement his own options.

(MAKEFILES OPTIONS FILES) [Function]
Performs (MAKEFILE FILE OPTIONS) for each file on FILES that needs to be dumped. If FILES= NIL, FILELST is used. For example, (MAKEFILES 'LIST) will make and list all files that have been changed. In this case, if any typed definitions for any items have been defined or changed and they are *not* contained in one of the files on FILELST, MAKEFILES calls ADDTOFILES? to allow the user to specify where these go. MAKEFILES returns a list of all files that are made.

(CLEANUP FILE₁ FILE₂ ... FILE_N) [NLambda NoSpread Function]
Dumps, lists, and recompiles (with RECOMPILE or BRECOMPILE) any of the specified files (unevaluated) requiring the corresponding operation. If no files are specified, FILELST is used. CLEANUP returns NIL.

CLEANUP uses the value of the variable CLEANUPOPTIONS as the OPTIONS argument to MAKEFILE. CLEANUPOPTIONS is initially (LIST RC), to indicate that the files should be listed and recompiled. If CLEANUPOPTIONS is set to (RC F), no listing will be performed, and no functions will be redefined as the result of compiling. Alternatively, if FILE₁ is a list, it will be interpreted as the list of options regardless of the value of CLEANUPOPTIONS.

(FILES?) [Function]
Prints on the terminal the names of those files that have been modified but not dumped, dumped but not listed, dumped but not compiled, plus the names of any functions and other typed definitions (if any) that are not contained in any file. If there are any, FILES? then calls ADDTOFILES? to allow the user to specify where these go.

(ADDTOFILES? _) [Function]
Called from MAKEFILES, CLEANUP, and FILES? when there are typed definitions that have been marked as changed which do not belong to any file. ADDTOFILES? lists the names of the changed items, and asks the user if he wants to specify where these items should be put. If user answers N(o), ADDTOFILES? returns NIL without taking any action. If the user answers], this is taken to be an answer to each question that would be asked, and all the changed items are marked as dummy items to be ignored. Otherwise, ADDTOFILES? prints the name of each

FILE PACKAGE

changed item, and accepts one of the following responses:

A le name or a variable whose value is a list

Adds the item to the corresponding le or list, using ADDTOFILE.

If the item is not the name of a le on FILELST, the user will be asked whether it is a new le. If he says no, then ADDTOFILES? will check whether the item is the name of a list, i.e. whether its value is a list. If not, the user will be asked whether it is a new list.

line-feed

Same as the user's previous response.

space or carriage return

Take no action.

] The item is marked as a dummy item by adding it to NILCOMS. This tells the le package simply to ignore this item.

[The "de nition" of the item in question is prettyprinted to the terminal, and then the user is asked again about its disposition.

(ADDTOFILES? prompts with 'LISTNAME: (', the user types in the name of a list, i.e. a variable whose value is a list, terminated by a). The item will then only be added to (under) a command in which the named list appears as a levar. If none are found, a message is printed, and the user is asked again. For example, the user de nes a new function FOO3, and when asked where it goes, types (FOOFNS). If the command (FNS * FOOFNS) is found, FOO3 will be added to the value of FOOFNS. If instead the user types (FOOCOMS), and the command (COMS * FOOCOMS) is found, then FOO3 will be added to a command for dumping functions that is contained in FOOCOMS.

Note: If the named list is not also the name of a le, the user can simply type it in without parenthesis as described above.

@ ADDTOFILES? prompts with "Near: (", the user types in the name of an object, and the item is then inserted in a command for dumping objects (of its type) that contains the indicated name. The item is inserted immediately after the indicated name.

(LISTFILES FILE₁ FILE₂ ... FILE_N) [NLambda NoSpread Function]
Lists each of the speci ed les (unevaluated). If no les are given, NOTLISTEDFILES is used. Each le listed is removed from NOTLISTEDFILES if the listing is completed. For each le not found, LISTFILES prints the message "FILENAME NOT FOUND" and proceeds to the next le. LISTFILES calls the function LISTFILES1 on each le to be listed. The user can advise or rede ne LISTFILES1 for more specialized applications.

(Interlisp- 10) LISTFILES uses the function TENEX (page 22.6) to tell the operating system to print the le. LISTFILES calls LISTFILES1 which calls TENEX with (CONCAT 'LIST\$ FILENAME LISTFILESTR), where LISTFILESTR is

Remaking a Symbolic File

initially ‘cr’. The user can reset LISTFILESTR to specify subcommands for the list command, or advise or redefine LISTFILES1.

(Interlisp- D) LISTFILES1 is initially defined as EMPRESS (page 18.17).

(COMPILEFILES FILE₁ FILE₂ ... FILE_N) [NLambda NoSpread Function]
Executes the RC and C options of MAKEFILE for each of the specified files (unevaluated). If no files are given, NOTCOMPILEDFILES is used. Each file compiled is removed from NOTCOMPILEDFILES. If FILE₁ is a list, it is interpreted as the OPTIONS argument to MAKEFILES. This feature can be used to supply an answer to the compiler’s LISTING? question, e.g., (COMPILEFILES (STF)) will compile each file on NOTCOMPILEDFILES so that the functions are redefined without the EXPRs definitions being saved.

(WHEREIS NAME TYPE FILES FN) [Function]
TYPE is a file package type. WHEREIS sweeps through all the files on the list FILES and returns a list of all files containing NAME as a TYPE. WHEREIS knows about and expands all file package commands and file package macros. TYPE = NIL defaults to FNS (to retrieve function definitions). If FILES is not a list, the value of FILELST is used.

If FN is given, it should be a function (with arguments NAME, FILE, and TYPE) which is applied for every file in FILES that contains NAME as a TYPE. In this case, WHEREIS returns NIL.

If the WHEREIS package (page 23.40) has been loaded, WHEREIS is redefined so that FILES= T means to use the whereis package data base, so WHEREIS will find NAME even if the file has not been loaded or noticed. FILES= NIL always means use FILELST.

11.2.1 Remaking a Symbolic File

Most of the time that a symbolic file is written using MAKEFILE, only a few of the functions that it contains have been changed since the last time the file was written. Rather than prettyprinting all of the functions, it is often considerably faster to “remake” the file, copying the prettyprinted definitions of unchanged functions from an earlier version of the symbolic file, and only prettyprinting those functions that have been changed.

MAKEFILE will remake the symbolic file if the REMAKE option is specified. If the NEW option is given, the file is not remade, and all of the functions are prettyprinted. The default action is specified by the value of MAKEFILEREMAKEFLG: if T (its initial value), MAKEFILE will remake files unless the NEW option is given; if NIL, MAKEFILE will not remake unless the REMAKE option is given.

Note: If the file has never been loaded or dumped, for example if the lecons were simply set up in memory, then MAKEFILE will never attempt to remake the file, regardless of the setting of MAKEFILEREMAKEFLG, or whether the REMAKE option was specified.

When MAKEFILE is remaking a symbolic file, the user can explicitly indicate the functions which are to be prettyprinted and the file to be used for copying the rest of the function definitions from via the REPRINTFNS and SOURCEFILE arguments to MAKEFILE. Normally, both of these arguments are defaulted to NIL. In this case, REPRINTFNS will be set to those functions that have been changed since the last

FILE PACKAGE

version of the `le` was written. For `SOURCEFILE`, `MAKEFILE` obtains the full name of the most recent version of the `le` (that it knows about) from the `FILEDATES` property of the `le`, and checks to make sure that the `le` still exists and has the same `le` date as that stored on the `FILEDATES` property. If it does, `MAKEFILE` uses that `le` as `SOURCEFILE`. This procedure permits the user to `LOAD` or `LOADFROM` a `le` in a different directory, and still be able to remake the `le` with `MAKEFILE`. In the case where the most recent version of the `le` cannot be found, `MAKEFILE` will attempt to remake using the *original* version of the `le` (i.e., the one first loaded), specifying as `REPRINTFNS` the union of all changes that have been made since the `le` was first loaded, which is obtained from the `FILECHANGES` property of the `le`. If both of these fail, `MAKEFILE` prints the message ‘CAN’T FIND EITHER THE PREVIOUS VERSION OR THE ORIGINAL VERSION OF FILE, SO IT WILL HAVE TO BE WRITTEN ANEW’, and does not remake the `le`, i.e. will prettyprint all of the functions.

When a remake is specified, `MAKEFILE` also checks to see how the `le` was originally loaded (see page 11.12). If the `le` was originally loaded as a compiled `le`, `MAKEFILE` will automatically call `LOADVARS` to obtain those `DECLARE:` expressions that are contained on the symbolic `le`, but not the compiled `le`, and hence have not been loaded. If the `le` was loaded by `LOADFNS` (but not `LOADFROM`), then `LOADVARS` will automatically be called to obtain any non-`DEFINEQ` expressions.

Note: Remaking a symbolic `le` is considerably faster if the earlier version has a *le map* indicating where the function definitions are located (page 11.38), but it does not depend on this information.

11.3 MARKING CHANGES

The `le` package needs to know what typed definitions have been changed, so it can determine which `les` need to be updated. This is done by “marking changes”. All the system functions that perform `le` package operations (`LOAD`, `TCOMPL`, `PRETTYDEF`, etc.), as well as those functions that define or change data, (`EDITF`, `EDITV`, `EDITP`, `DWIM` corrections to user functions) interact with the `le` package by marking changes. Also, *typed-in* assignment of variables or property values is noticed by the `le` package. (Note that if a program modifies a variable or property value, this is not noticed.) In some cases the marking procedure can be subtle, e.g. if the user edits a property list using `EDITP`, only those properties whose values are actually changed (or added) are marked.

The various system functions which create or modify objects call `MARKASCHANGED` to mark the object as changed. For example, when a function is defined via `DEFINE` or `DEFINEQ`, or modified via `EDITF`, or a `DWIM` correction, the function is marked as being a changed object of type `FNS`. Similarly, whenever a new record is declared, or an existing record redeclared or edited, it is marked as being a changed object of type `RECORDS`, and so on for all of the other `le` package types.

The user can also call `MARKASCHANGED` directly to mark objects of a particular `le` package type as changed:

```
(MARKASCHANGED NAME TYPE REASON ) [Function]
  Marks NAME of type TYPE as being changed. REASON is a listatom that indicated
  how NAME was changed. MARKASCHANGED recognizes the following values for
  REASON :
```

DEFINED	Used to indicate the creation of NAME , e.g. from DEFINE.
CHANGED	Used to indicate a change to NAME , e.g. from the editor.

Noticing Files

DELETED Used to indicate the deletion of `NAME`, e.g. by `DELDEF`.

CLISP Used to indicate the modification of `NAME` by CLISP translation.

For backwards compatibility, `MARKASCHANGED` also accepts a `REASON` of `T` (= `DEFINED`) and `NIL` (= `CHANGED`). New programs should avoid using these values.

`MARKASCHANGED` returns `NAME`. `MARKASCHANGED` is undoable.

(`UNMARKASCHANGED` `NAME` `TYPE`) [Function]
Unmarks `NAME` of type `TYPE` as being changed. Returns `NAME` if `NAME` was marked as changed and is now unmarked, `NIL` otherwise. `UNMARKASCHANGED` is undoable.

(`FILEPKGCHANGES` `TYPE` `LST`) [NoSpread Function]
If `LST` is not specified (as opposed to being `NIL`), returns a list of those objects of type `TYPE` that have been marked as changed but not yet associated with their corresponding files (See page 11.14). If `LST` is specified, `FILEPKGCHANGES` sets the corresponding list. (`FILEPKGCHANGES`) returns a list of *all* objects marked as changed as a list of elements of the form (`TYPE``NAME` . `CHANGEDOBJECTS`).

Some properties (e.g. `EXPR`, `ADVICE`, `MACRO`, `I.S.OPR`, etc..) are used to implement other file package types. For example, if the user changes the value of the property `I.S.OPR`, he is really changing an object of type `I.S.OPR`, and the effect is the same as though he had redefined the `i.s.opr` via a direct call to the function `I.S.OPR`. If a property whose value has been changed or added does not correspond to a specific file package type, then it is marked as a changed object of type `PROPS` whose *name* is (`VARIABLENAME` `PROPNAME`) (except if the property name has a property `PROTYPE` with value `IGNORE`).

Similarly, if the user changes a variable which implements the file package type `ALISTS` (as indicated by the appearance of the property `VARTYPE` with value `ALIST` on the variable's property list), only those entries that are actually changed are marked as being changed objects of type `ALISTS`, and the "name" of the object will be (`VARIABLENAME` `KEY`) where `KEY` is `CAR` of the entry on the alist that is being marked. If the variable corresponds to a specific file package type other than `ALISTS`, e.g. `USERMACROS`, `LISPXMACROS`, etc., then an object of that type is marked. In this case, the name of the changed object will be `CAR` of the corresponding entry on the alist. For example, if the user edits `LISPXMACROS` and changes a definition for `PL`, then the object `PL` of type `LISPXMACROS` is marked as being changed.

11.4 NOTICING FILES

Already existing files are "noticed" by `LOAD` or `LOADFROM` (or by `LOADFNS` or `LOADVARS` when the `VARS` argument is `T`). New files are noticed when they are constructed by `MAKEFILE`, or when definitions are first associated with them via `FILES?` or `ADDTOFILES?`. Noticing a file updates certain lists and properties so that the file package functions know to include the file in their operations. For example, `CLEANUP` will only dump files that have been noticed.

The file package uses information stored on the property list of the root name of noticed files. The following property names are used:

FILE PACKAGE

FILE [Property Name]
When a le is noticed, the property **FILE**, value ((**FILECOMS** . **LOADTYPE**)) is added to the property list of its root name. **FILECOMS** is the variable containing the lecoms of the le (see page 11.21). **LOADTYPE** indicates *how* the le was loaded, e.g., completely loaded, only partially loaded as with **LOADFNS**, loaded as a compiled le, etc.

The property **FILE** is used to determine whether or not the corresponding le has been modified since the last time it was loaded or dumped. CDR of the **FILE** property records by type those items that have been changed since the last **MAKEFILE**. Whenever a le is dumped, these items are moved to the property **FILECHANGES**, and CDR of the **FILE** property is reset to **NIL**.

FILECHANGES [Property Name]
The property **FILECHANGES** contains a list of all changed items since the le was loaded (there may have been several sequences of editing and rewriting the le). When a le is dumped, the changes in CDR of the **FILE** property are added to the **FILECHANGES** property.

FILEDATES [Property Name]
The property **FILEDATES** contains a list of version numbers and corresponding le dates for this le. These version numbers and dates are used for various integrity checks in connection with *remaking* a le (see page 11.10).

FILEMAP [Property Name]
The property **FILEMAP** is used to store the lemap for the le (see page 11.38). This is used to directly load individual functions from the middle of a le.

To compute the root name, **ROOTFILENAME** is applied to the name of the le as indicated in the **FILECREATED** expression appearing at the front of the le, since this name corresponds to the name the le was originally made under. The le package detects that the le being noticed is a compiled le (regardless of its name), by the appearance of more than one **FILECREATED** expressions. In this case, each of the les mentioned in the following **FILECREATED** expressions are noticed. For example, if the user performs (**BCOMPL** '(**FOO FIE**)), and subsequently loads **FOO.DCOM**, both **FOO** and **FIE** will be noticed.

When a le is noticed, its root name is added to the list **FILELST**:

FILELST [Variable]
Contains a list of the root names of the les that have been noticed.

LOADEDFILELST [Variable]
Contains a list of the actual names of the les as loaded by **LOAD**, **LOADFNS**, etc. For example, if the user performs (**LOAD** '<**NEWLISP**>**EDITA.COM**;3), **EDITA** will be added to **FILELST**, but <**NEWLISP**>**EDITA.COM**;3 is added to **LOADEDFILELST**. **LOADEDFILELST** is not used by the le package; it is maintained solely for the user's benefit.

Distributing Change Information

11.5 DISTRIBUTING CHANGE INFORMATION

Periodically, the function `UPDATEFILES` is called to find which file(s) contain the elements that have been changed. `UPDATEFILES` is called by `FILES?`, `CLEANUP`, and `MAKEFILES`, i.e., any procedure that requires the `FILE` property to be up to date. This procedure is followed rather than update the `FILE` property after each change because scanning `FILELST` and examining each file package command can be a time-consuming process, and is not so noticeable when performed in conjunction with a large operation like loading or writing a file.

`UPDATEFILES` operates by scanning `FILELST` and interrogating the file package commands for each file. When (if) any files are found that contain the corresponding typed definition, the name of the element is added to the value of the property `FILE` for the corresponding file. Thus, after `UPDATEFILES` has completed operating, the files that need to be dumped are simply those files on `FILELST` for which `CDR` of their `FILE` property is non-`NIL`. For example, if the user loads the file `FOO` containing definitions for `FOO1`, `FOO2`, and `FOO3`, edits `FOO2`, and then calls `UPDATEFILES`, `(GETPROP 'FOO 'FILE)` will be `((FOOCOMS . T) (FNS FOO2))`. If any objects marked as changed have not been transferred to the `FILE` property for some file, e.g., the user defines a new function but forgets (or declines) to add it to the file package commands for the corresponding file, then both `FILES?` and `CLEANUP` will print warning messages, and then call `ADDTOFILES?` to permit the user to specify on which files these items belong.

The user can also invoke `UPDATEFILES` directly:

```
(UPDATEFILES _ _ ) [Function]
  (UPDATEFILES) will update the FILE properties of the noticed files.
```

11.6 FILE PACKAGE TYPES

In addition to the definitions of functions and values of variables, source files in Interlisp can contain a variety of other information, e.g. property lists, record declarations, macro definitions, hash arrays, etc. In order to treat such a diverse assortment of data uniformly from the standpoint of file operations, the file package uses the concept of a *typed definition*, of which a function definition is just one example. A typed definition associates with a name (usually a lisp atom), a definition of a given type (called the file package type). Note that the same name may have several definitions of different types. For example, a lisp atom may have both a function definition and a variable definition. The file package also keeps track of the file that a particular typed definition is stored on, so one can think of a typed definition as a relation between four elements: a name, a definition, a type, and a file.

A file package type is an abstract notion of a class of objects which share the property that every object of the same file package type is stored, retrieved, edited, copied etc., by the file package in the same way. Each file package type is identified by a lisp atom, which can be given as an argument to the functions that manipulate typed definitions. The user may define new file package types, as described in page 11.20.

```
FILEPKGTYPES [Variable]
  The value of FILEPKGTYPES is a list of all file package types, including any that may have been defined by the user.
```

The file package is initialized with the following built-in file package types:

FILE PACKAGE

FNS	Function definitions.
VAR	(top-level) Variable values.
PROPS	<p>Property name/value pairs. When a property is changed or added, an object of type PROPS, with “name” (LITATOM PROPNAM) is marked as being changed.</p> <p>Note that some properties are used to implement other le package types. For example, the property MACRO implements the le package type MACROS, the property ADVICE implements ADVICE, etc. This is indicated by putting the property PROPTYPE, with value of the le package type on the property list of the property name. For example, (GETPROP 'MACRO 'PROPTYPE) => MACROS. When such a property is changed or added, an object of the corresponding le package type is marked. If (GETPROP PROPNAM 'PROPTYPE) => IGNORE, the change is ignored. The FILE, FILEMAP, FILEDATES, etc. properties are all handled this way. (Note that IGNORE cannot be the name of a le package type implemented as a property).</p>
ALISTS	<p>Alists (association lists); a list of dotted pairs accessed via ASSOC and PUTASSOC.</p> <p>A variable is declared to have an association list as its value by putting on its property list the property VARTYPE with value ALIST. In this case, each dotted pair on the list is an object of type ALISTS. When the value of such a variable is changed, only those entries in the a-list that are actually changed or added are marked as changed objects of type ALISTS (with “name” (LITATOM KEY)). Objects of type ALISTS are dumped via the ALISTS or ADDVARS le package commands.</p> <p>Note that some alists are used to “implement” other le package types. For example, the value of the global variable USERMACROS implements the le package type USERMACROS and the values of LISPXMACROS and LISPXHISTORYMACROS implement the le package type LISPXMACROS. This is indicated by putting on the property list of the variable the property VARTYPE with value a list of the form (ALIST FILEPKGTYPE). For example, (GETPROP 'LISPXHISTORYMACROS 'VARTYPE) => (ALIST LISPXMACROS).</p>
EXPRESSIONS	<p>Expressions.</p> <p>Objects of type EXPRESSIONS are written out via the P le package command, and marked as being changed via the REMEMBER programmers assistant command (page 8.13).</p>
MACROS	Compiler macros. See page 5.17.
USERMACROS	User edit macros. See page 17.48.
LISPXMACROS	(values in) LISPXMACROS and LISPXHISTORYMACROS. See page 8.19.
ADVICE	Advice. See page 10.7.
FILEPKGCOMS	File package commands/types. New le package types and commands can be defined as explained on page 11.20 and page 11.32.

Functions for Manipulating Typed Definitions

RECORDS	Record declarations. See page 3.1.
FIELDS	Fields of records. The “definition” of an object of type FIELDS is a list of all the record declarations which contain the name. See page 3.1.
I.S.OPRS	Iterative statement operators. See page 4.5.
TEMPLATES	Masterscope templates. See page 13.1.
FILES	Files. Files may be treated like other typed definitions.
FILEVARS	Filevars. See page 11.30.

11.6.1 Functions for Manipulating Typed Definitions

The functions described below can be used to manipulate typed definitions, without needing to know how the manipulations are done. For example, (GETDEF 'FOO 'FNS) will return the function definition of FOO, (GETDEF 'FOO 'VARS) will return the variable value of FOO, etc. All of the functions use the following conventions:

- (1) Any argument that expects a list of literals will also accept a single literal, operating as though it were enclosed in a list. For example, if the argument FILES should be a list of files, it may also be a single file.
- (2) TYPE is a file package type. TYPE = NIL is equivalent to TYPE = FNS. The singular form of a file package type is also recognized, e.g. TYPE = VAR is equivalent to TYPE = VARS.
- (3) FILES = NIL is equivalent to FILES = FILELST.
- (4) SOURCE is used to indicate the source of a definition, that is, where the definition should be found. SOURCE can be one of:

CURRENT Get the definition currently in effect.

SAVED Get the “saved” definition, as stored by SAVEDEF (page 11.18).

FILE Get the definition contained on the (rst) file determined by WHEREIS (page 11.10).

Note: WHEREIS is called with FILES = T, so that if the WHEREIS package (page 23.40) is loaded, the WHEREIS data base will be used to find the file containing the definition.

? Get the definition currently in effect if there is one, else the saved definition if there is one, otherwise the definition from a file determined by WHEREIS. Like specifying CURRENT, SAVED, and FILE in order, and taking the first definition that is found.

a file name or list of file names

Get the definition from the first of the indicated files that contains one.

NIL In most cases, giving SOURCE = NIL (or not specifying it at all) is the same as giving ?, to get either the current, saved, or listed definition. However, with HASDEF, SOURCE = NIL is interpreted as equal to SOURCE = CURRENT, which only tests if

FILE PACKAGE

there is a current definition.

(5) All functions which make destructive changes are undoable.

The operation of most of the functions described below can be changed or extended by modifying the appropriate properties for the corresponding file package type using the function `FILEPKGTYPE`, described on page 11.20.

`(GETDEF NAME TYPE SOURCE OPTIONS)` [Function]
Returns the definition of `NAME`, of type `TYPE`, from `SOURCE`. For most types, `GETDEF` returns the expression which would be prettyprinted when dumping `NAME` as `TYPE`. For example, for `TYPE = FNS`, an `EXPR` definition is returned, for `TYPE = VARS`, the value of `NAME` is returned, etc.

`OPTIONS` is a list which specifies certain options:

`NOERROR` `GETDEF` causes an error if an appropriate definition cannot be found, unless `OPTIONS` is or contains `NOERROR`.

a string If `OPTIONS` is or contains a string, that string will be returned if no definition is found. The caller can thus determine whether a definition was found, even for types for which `NIL` or `NOBIND` are acceptable definitions.

`NOCOPY` `GETDEF` returns a copy of the definition unless `OPTIONS` is or contains `NOCOPY`.

`NODWIM` A `FNS` definition will be dwimmed if it is likely to contain `CLISP` unless `OPTIONS` is or contains `NODWIM`.

`(PUTDEF NAME TYPE DEFINITION)` [Function]
Defines `NAME` of type `TYPE` with `DEFINITION`. For `TYPE = FNS`, does a `DEFINE`; for `TYPE = VARS`, does a `SAVESET`, etc.

For `TYPE = FILES`, `PUTDEF` establishes the command list, notices `NAME`, and then calls `MAKEFILE` to actually dump the file `NAME`, copying functions if necessary from the "old" file (supplied as part of `DEFINITION`).

`(HASDEF NAME TYPE SOURCE SPELLFLAG)` [Function]
Returns `NAME` if `NAME` is the name of something of type `TYPE`. If not, attempts spelling correction if `SPELLFLAG = T`, and returns the spelling-corrected `NAME`. Otherwise returns `NIL`.

`(HASDEF NIL TYPE)` returns `T` if `NIL` has a valid definition.

Note: if `SOURCE = NIL`, `HASDEF` interprets this as equal to `SOURCE = CURRENT`, which only tests if there is a current definition.

`(TYPESOF NAME POSSIBLETYPES IMPOSSIBLETYPES SOURCE)` [Function]
Returns a list of the types in `POSSIBLETYPES` but not in `IMPOSSIBLETYPES` for which `NAME` has a definition. `FILEPKGTYPES` is used if `POSSIBLETYPES` is `NIL`.

Functions for Manipulating Typed Definitions

(COPYDEF OLD NEW TYPE SOURCE OPTIONS) [Function]

Defines NEW to have a copy of the definition of OLD by doing PUTDEF on a copy of the definition retrieved by (GETDEF OLD TYPE SOURCE OPTIONS). NEW is substituted for OLD in the copied definition, in a manner that may depend on the TYPE.

For example, (COPYDEF 'PDQ 'RST 'FILES) sets up RSTCOMS to be a copy of PDQCOMS, changes things like (VARS * PDQVARS) to be (VARS * RSTVARS) in RSTCOMS, and performs a MAKEFILE on RST such that the appropriate definitions get copied from PDQ.

Note: COPYDEF disables the NOCOPY option of GETDEF, so NEW will always have a copy of the definition of OLD.

(DELDEF NAME TYPE) [Function]

Removes the definition of NAME as a TYPE that is currently in effect.

(SHOWDEF NAME TYPE FILE) [Function]

Prettyprints the definition of NAME as a TYPE to FILE. This shows the user how NAME would be written to a file. Used by ADDTOFILES? (page 11.8).

(EDITDEF NAME TYPE SOURCE EDITCOMS) [Function]

Edits the definition of NAME as a TYPE. Essentially performs (PUTDEF NAME TYPE (EDITE (GETDEF NAME TYPE SOURCE) EDITCOMS)).

(SAVEDEF NAME TYPE DEFINITION) [Function]

Makes DEFINITION (or if DEFINITION = NIL, the definition of NAME as a TYPE that is currently in effect) be the "saved" definition for NAME as a TYPE. If TYPE = FNS (or TYPE = NIL), this consists of storing DEFINITION on NAME's property list under property EXPR, CODE, or SUBR. For TYPE = VARS, the definition is stored as the value of the VALUE property. For other types, DEFINITION is stored in an internal data structure, from where it can be retrieved by GETDEF or UNSAVEDEF.

(UNSAVEDEF NAME TYPE _) [Function]

Makes the "saved" definition of NAME as a TYPE be the definition currently in effect. If TYPE = FNS (or TYPE = NIL), UNSAVEDEF will unsave the EXPR property if any, else CODE or SUBR. UNSAVEDEF also recognizes TYPE = EXPR, CODE, or SUBR, meaning to unsave the corresponding definition only.

(LOADDEF NAME TYPE SOURCE) [Function]

Equivalent to (PUTDEF NAME TYPE (GETDEF NAME TYPE SOURCE)). LOADDEF is essentially a generalization of LOADFNS, e.g. it enables loading a single record declaration from a file. Note that (LOADDEF FN) will give FN an EXPR definition, either obtained from its property list or a file, unless it already has one.

(CHANGEALLERS OLD NEW TYPES FILES METHOD) [Function]

Finds all of the places where OLD is used as any of the types in TYPES and changes those places to use NEW. For example, (CHANGEALLERS 'NLSETQ 'ERSETQ) will change all calls to NLSETQ to be calls to ERSETQ. Also changes occurrences of OLD to NEW inside the lecoms of any file, inside record declarations, properties, etc.

FILE PACKAGE

CHANGECALLERS attempts to determine if OLD might be used as more than one type; for example, if it is both a function and a record eld. If so, rather than performing the transformation OLD -> NEW automatically, the user is allowed to edit all of the places where OLD occurs. For each occurrence of OLD, the user is asked whether he wants to make the replacement. If he responds with anything except Yes or No, the editor is invoked on the expression containing that occurrence.

Currently there are two different methods for determining which functions are to be examined. If METHOD = EDITCALLERS, EDITCALLERS is used to search FILES (see page 17.59). If METHOD = MASTERSCOPE, then the Masterscope database is used instead. METHOD = NIL defaults to MASTERSCOPE if the value of the variable DEFAULTRENAMEMETHOD is MASTERSCOPE and a Masterscope database exists, otherwise it defaults to EDITCALLERS.

(RENAME OLD NEW TYPES FILES METHOD) [Function]
First performs (COPYDEF OLD NEW TYPE) for all TYPE inside TYPES. It then calls CHANGECALLERS to change all occurrences of OLD to NEW, and then “deletes” OLD with DELDEF. For example, if the user has a function FOO which he now wishes to call FIE, he simply performs (RENAME 'FOO 'FIE), and FIE will be given FOO's definition, and all places that FOO are called will be changed to call FIE instead.

(COMPARE NAME1 NAME2 TYPE SOURCE1 SOURCE2) [Function]
Compares definition of NAME1 with that of NAME2, i.e. performs (COMPARELISTS (GETDEF NAME1 TYPE SOURCE1) (GETDEF NAME2 TYPE SOURCE2))

(COMPAREDEFS NAME TYPE SOURCES) [Function]
Calls COMPARELISTS on all pairs of definitions of NAME as a TYPE obtained from the various SOURCES.

11.6.2 Defining New File Package Types

All manipulation of typed definitions in the le package is done using the type-independent functions GETDEF, PUTDEF, etc. Therefore, to define a new le package type, it is only necessary to specify what these functions should do when dealing with a typed definition of the new type. Each le package type has the following properties, whose values are functions or lists of functions:

Note: These functions are defined to take a TYPE argument so that the user may have the same function for more than one type.

GETDEF Value is a function of three arguments, NAME, TYPE, and OPTIONS, which should return the current definition of NAME as a type TYPE. Used by GETDEF (which passes its OPTION argument).

If there is no GETDEF property, a le package command for dumping NAME is created (by MAKENEWCOM). This command is then used to write the definition of NAME as a type TYPE onto the le FILEPKG.SCRATCH (in Interlisp-D, this le is created on the {CORE} device). This expression is then read back in and returned as the current definition.

Defining New File Package Types

FILEGETDEF	This enables the user to provide a way of obtaining definitions from a file that is more efficient than the default procedure used by GETDEF. Value is a function of four arguments, NAME, TYPE, FILE, and OPTIONS. The function is applied by GETDEF when it is determined that a typed definition is needed from a particular file. The function must open and search the given file and return any TYPE definition for NAME that it finds.
PUTDEF	Value is a function of three arguments, NAME, TYPE, and DEFINITION, which should store DEFINITION as the definition of NAME as a type TYPE. Used by PUTDEF.
DELDEF	Value is a function of two arguments, NAME, and TYPE, which removes the definition of NAME as a TYPE that is currently in effect. Used by DELDEF.
NEWCOM	Value is a function of four arguments, NAME, TYPE, LISTNAME, and FILE. Specifies how to make a new (instance of a) file package command to dump NAME, an object of type TYPE. The function should return the new file package command. Used by ADDTOFILE and SHOWDEF. If LISTNAME is non-NIL, this means that the user specified LISTNAME as the lever in his interaction with ADDTOFILES? (see page 11.30). If no NEWCOM is specified, the default is to call DEFAULTMAKENEWCOM, which will construct and return a command of the form (TYPE NAME). DEFAULTMAKENEWCOM can be advised or redefined by the user.
WHENCHANGED	Value is a list of functions to be applied to NAME, TYPE, and REASON when NAME, an instance of type TYPE, is changed or defined (see MARKASCHANGED, page 11.11). Used for various applications, e.g. when an object of type I.S.OPRS changes, it is necessary to clear the corresponding translations from CLISPARRAY. The WHENCHANGED functions are called before the object is marked as changed, so that it can, in fact, decide that the object is <i>not</i> to be marked as changed, and execute (RETFROM 'MARKASCHANGED). Note: For backwards compatibility, the REASON argument passed to WHENCHANGED functions is either T (for DEFINED) and NIL (for CHANGED).
WHENFILED	Value is a list of functions to be applied to NAME, TYPE, and FILE when NAME, an instance of type TYPE, is added to FILE.
WHENUNFILED	Value is a list of functions to be applied to NAME, TYPE, and FILE when NAME, an instance of type TYPE, is removed from FILE.
DESCRIPTION	Value is a string which describes instances of this type. For example, for type RECORDS, the value of DESCRIPTION is the string "record declarations".

The function FILEPKGTYPE is used to define new file package types, or to change the attributes of existing types. Note that it is possible to redefine the attributes of system file package types, such as FNS or PROPS.

(FILEPKGTYPE TYPE PROP₁ VAL₁ PROP_N VAL_N) [NoSpread Function]
 Nospread function for defining new file package types, or changing attributes of existing file package types. PROP_i is one of the property names given above; VAL_i

FILE PACKAGE

is the value to be given to that property. Returns `TYPE`.

`(FILEPKGTYPE TYPE PROP)` returns the value of the property `PROP`, without changing it.

`(FILEPKGTYPE TYPE)` returns an alist of all of the defined properties of `TYPE`, using the property names as keys.

11.7 FILE PACKAGE COMMANDS

The basic mechanism for creating symbolic lisp files is the function `MAKEFILE` (page 11.6). For each file, the file package has a data structure known as the “lecoms”, which specifies what typed descriptions are contained in the file. A lecoms is a list of file package commands, each of which specifies objects of a certain file package type which should be dumped. For example, the lecoms

```
( (FNS FOO)
  (VARS FOO BAR BAZ)
  (RECORDS XYZZY) )
```

has a `FNS`, a `VARS`, and a `RECORDS` file package command. This lecoms specifies that the function definition for `FOO`, the variable values of `FOO`, `BAR`, and `BAZ`, and the record declaration for `XYZZY` should be dumped.

By convention, the lecoms of a file `x` is stored as the value of the lisp atom `xCOMS`. For example, `(MAKEFILE 'FOO. ;27)` will use the value of `FOOCOMS` as the lecoms. This variable can be directly manipulated, but the file package contains facilities which make constructing and updating lecoms easier, and in some cases automatic (See page 11.32).

A file package command is an instruction to `MAKEFILE` to perform an explicit, well-defined operation, usually printing an expression. Usually there is a one-to-one correspondence between file package types and file package commands; for each file package type, there is a file package command which is used for writing objects of that type to a file, and each file package command is used to write objects of a particular type. However, in some cases, the same file package type can be dumped by several different file package commands. For example, the file package commands `PROP`, `IFPROP`, and `PROPS` all dump out objects with the file package type `PROPS`. This means if the user changes an object of file package type `PROPS` via `EDITP`, a typed-in call to `PUTPROP`, or via an explicit call to `MARKASCHANGED`, this object can be written out with any of the above three commands. Thus, when the file package attempts to determine whether this typed object is contained on a particular file, it must look at instances of all three file package commands `PROP`, `IFPROP`, and `PROPS`, to see if the corresponding atom and property are specified. It is also permissible for a single file package command to dump several different file package types. For example, the user can define a file package command which dumps both a function definition and its macro. Conversely, some file package commands do not dump any file package types at all, such as the `E` command.

For each file package command, the file package must be able to determine what typed definitions the command will cause to be printed so that the file package can determine on what file (if any) an object of a given type is contained (by searching through the lecoms). Similarly, for each file package type, the file package must be able to construct a command that will print out an object of that type. In other words, the file package must be able to map file package commands into file package types, and vice

File Package Commands

versa. Information can be provided to the `le` package about a particular `le` package command via the function `FILEPKGCOM` (page 11.32), and information about a particular `le` package type via the function `FILEPKGTYPE` (page 11.20). In the absence of other information, the default is simply that a `le` package command of the form `(X NAME)` prints out the definition of `NAME` as a type `X`, and, conversely, if `NAME` is an object of type `X`, then `NAME` can be written out by a command of the form `(X NAME)`.

If a `le` package function is given a command or type that is not defined, it attempts spelling correction⁵ using `FILEPKGCOSPLST` as a spelling list. If successful, the corrected version of the list of `le` package commands is written (again) on the output `le`.⁶ If unsuccessful, generates an error, `BAD FILE PACKAGE COMMAND`.

File package commands can be used to save on the output `le` definitions of functions, values of variables, property lists of atoms, advised functions, edit macros, record declarations, etc. The interpretation of each `le` package command is as follows:

`(FNS FN1 FNN)` [File Package Command]
Writes a `DEFINEQ` expression with the function definitions of `FN1 FNN`.

The user should never print a `DEFINEQ` expression directly onto a `le` himself (by using the `P` `le` package command, for example), because `MAKEFILE` generates the lemap of function definitions from the `FNS` `le` package commands (see page 11.38).

`(VARS VAR1 VARN)` [File Package Command]
For each `VARi` writes an expression to set its top level value when the `le` is loaded. If `VARi` is atomic, `VARS` writes out an expression to set `VARi` to the top-level value it had at the time the `le` was written. If `VARi` is non-atomic, it is interpreted as `(VAR FORM)`, and `VARS` write out an expression to set `VAR` to the value of `FORM` (evaluated when the `le` is loaded).

`VARS` prints out expressions using `RPAQQ` and `RPAQ`, which are like `SETQQ` and `SETQ` except that they also perform some special operations with respect to the `le` package (see page 11.37).

Note: `VARS` cannot be used for putting arbitrary variable values on `les`. For example, if the value of a variable is an array (or many other data types), a listom which represents the array is dumped in the `le` instead of the array itself. The `HORRIBLEVARS` `le` package command (page 11.25) provides a way of saving and reloading variables whose values contain re-entrant or circular list structure, user data types, arrays, or hash arrays.

`(INITVARS VAR1 VARN)` [File Package Command]
`INITVARS` is used for initializing variables, setting their values only when they are currently `NOBIND`. A variable value defined in an `INITVARS` command will not change an already established value. This means that re-loading `les` to get some other information will not automatically revert to the initialization values.

⁵unless `DWIMFLG` or `NOSPELLFLG=NIL`. See page 15.12.

⁶since at this point, the uncorrected list of `le` package commands would already have been printed on the output `le`. When the `le` is loaded, this will result in `FILECOMS` being reset, and may cause a message to be printed, e.g., `(FOOCOMS RESET)`. The value of `FOOCOMS` would then be the corrected version.

FILE PACKAGE

The format of an INITVARS command is just like VARS. The only difference is that if VAR_i is atomic, the current value is not dumped; instead NIL is defined as the initialization value. Therefore, (INITVARS FOO (FUM 2)) is the same as (VARS (FOO NIL)(FUM 2)), if FOO and FUM are both NOBIND.

INITVARS writes out an RPAQ? expression on the line instead of RPAQ or RPAQQ.

(ADDVARS (VAR₁ . LST₁) (VAR_N . LST_N)) [File Package Command]

For each (VAR_i . LST_i), writes an ADDTOVAR to add each element of LST_i to the list that is the value of VAR_i at the time the line is loaded. The new value of VAR_i will be the union of its old value and LST_i. If the value of VAR_i is NOBIND, it is first set to NIL.

For example, (ADDVARS (DIRECTORIES LISP LISPUSERS)) will add LISP and LISPUSERS to the value of DIRECTORIES.

If LST_i is not specified, VAR_i is initialized to NIL if its current value is NOBIND. In other words, (ADDVARS (VAR)) will initialize VAR to NIL if VAR has not previously been set.

(ALISTS (VAR₁ KEY₁ KEY₂) (VAR_N KEY₃ KEY₄)) [File Package Command]

VAR_i is a variable whose value is an alist, such as EDITMACROS, BAKTRACELST, etc. For each VAR_i ALISTS writes out expressions which will restore the values associated with the specified keys. For example, (ALISTS (BREAKMACROS BT BTV)) will dump the definition for the BT and BTV commands on BREAKMACROS.

Some alists (USERMACROS, LISPXMACROS, etc.) are used to implement other line package types, and they have their own line package commands.

(PROP PR OPNAME LITATOM₁ LITATOM_N) [File Package Command]

Writes a PUTPROPS expression to restore the value of the PR OPNAME property of each litatom LITATOM_i when the line is loaded.

If PR OPNAME is a list, expressions will be written for each property on that list. If PR OPNAME is the litatom ALL, the values of all user properties (on the property list of each LITATOM_j) are saved. SYSPROPS is a list of properties used by system functions. Only properties *not* on that list are dumped when the ALL option is used.

If LITATOM_i does not have the property PR OPNAME (as opposed to having the property with value NIL), a warning message "NO PR OPNAME PROPERTY FOR LITATOM_i" is printed. The command IFPROP can be used if it is not known whether or not an atom will have the corresponding property.

(IFPROP PR OPNAME LITATOM₁ LITATOM_N) [File Package Command]

Same as the PROP line package command, except that it only saves the properties that actually appear on the property list of the corresponding atom. For example, if FOO1 has property PROP1 and PROP2, FOO2 has PROP3, and FOO3 has property PROP1 and PROP3, then (IFPROP (PROP1 PROP2 PROP3) FOO1 FOO2 FOO3) will save only those *ve* property values.

File Package Commands

- (PROPS (LITATOM ₁ PROPNAME ₁) (LITATOM _N PROPNAME _N)) [File Package Command]
Similar to PROP command. Writes a PUTPROPS expression to restore the value of PROPNAME _i for each LITATOM _i when the le is loaded.
- As with the PROP command, if LITATOM _i does not have the property PROPNAME (as opposed to having the property with NIL value), a warning message "NO PROPNAME _i PROPERTY FOR LITATOM _i" is printed.
- (P EXP ₁ EXP _N) [File Package Command]
Writes each of the expressions EXP ₁ EXP _N on the output le, where they will be evaluated when the le is loaded.
- (E FORM ₁ FORM _N) [File Package Command]
Each of the forms FORM ₁ FORM _N is evaluated at *output* time, when MAKEFILE interpretes this le package command.
- (COMS COM ₁ COM _N) [File Package Command]
Each of the commands COM ₁ COM _N is interpreted as a le package command.
- (* . TEXT) [File Package Command]
Used for inserting comment in a le. The le package command is simply written on the output le; it will be ignored when the le is loaded.
- If the rst element of TEXT is another *, a form-feed is printed on the le before the comment.
- (ADVISE FN ₁ FN _N) [File Package Command]
For each function FN _i writes expressions to reinstate the function to its advised state when the le is loaded. See page 10.7.
- (ADVICE FN ₁ FN _N) [File Package Command]
For each function FN _i writes a PUTPROPS expression which will put the advice back on the property list of the function. The user can then use READVICE to reactivate the advice.
- (USERMACROS LITATOM ₁ LITATOM _N) [File Package Command]
Each litatom LITATOM _i is the name of a user edit macro. Writes expressions to add the edit macro definitions of LITATOM _i to USERMACROS, and adds the names of the commands to the appropriate spelling lists.
- If LITATOM _i is not a user macro, a warning message "no EDIT MACRO for LITATOM _i" is printed.
- (FILEPKGCOMS LITATOM ₁ LITATOM _N) [File Package Command]
Each litatom LITATOM _i is either the name of a user-defined le package command or a user-defined le package type (or both). Writes expressions which will restore each command/type.
- If LITATOM _i is not a le package command or type, a warning message "no FILE PACKAGE COMMAND for LITATOM _i" is printed.
- (LISPXMACROS LITATOM ₁ LITATOM _N) [File Package Command]
Each LITATOM _i is defined on LISPXMACROS or LISPXHISTORYMACROS (see page

FILE PACKAGE

8.19). Writes expressions which will save and restore the definition for each macro, as well as making the necessary additions to LISPXCOMS

- (RECORDS REC₁ REC_N) [File Package Command]
Each REC_i is the name of a record (see page 3.1). Writes expressions which will redeclare the records when the file is loaded.
- (INITRECORDS REC₁ REC_N) [File Package Command]
Similar to RECORDS, INITRECORDS writes expressions on a file that will, when loaded, perform whatever initialization/allocation is necessary for the indicated records. However, the record declarations themselves are not written out. This facility is useful for building systems on top of Interlisp, in which the implementor may want to eliminate the record declarations from a production version of the system, but the allocation for these records must still be done.
- (I.S.OPRS OPR₁ OPR_N) [File Package Command]
Each OPR_i is the name of a user-defined i.s.opr (see page 4.13). Writes expressions which will redefine the i.s.oprs when the file is loaded.
- (TEMPLATES LITATOM₁ LITATOM_N) [File Package Command]
Each LITATOM_i is a litatom which has a Masterscope template (see page 13.18). Writes expressions which will restore the templates when the file is loaded.
- (BLOCKS BLOCK₁ BLOCK_N) [File Package Command]
For each BLOCK_i writes a DECLARE: expression which the block compile functions interpret as a block declaration. See page 12.14.
- (MACROS LITATOM₁ LITATOM_N) [File Package Command]
Each LITATOM_i is a litatom with a MACRO definition (and/or a DMACRO, 10MACRO, etc.). Writes out an expression to restore all of the macro properties for each LITATOM_i embedded in a DECLARE: EVAL@COMPILE so the macros will be defined when the file is compiled. See page 5.17.
- (SPECVARS VAR₁ VAR_N) [File Package Command]
(LOCALVARS VAR₁ VAR_N) [File Package Command]
(GLOBALVARS VAR₁ VAR_N) [File Package Command]
Outputs the corresponding compiler declaration embedded in a DECLARE: DOEVAL@COMPILE DONTCOPY. See page 12.3.
- (UGLYVARS VAR₁ VAR_N) [File Package Command]
Like VARS, except that the value of each VAR_i may contain structures for which READ is not an inverse of PRINT, e.g. arrays, readtables, user data types, etc. Uses HPRINT (page 6.24).
- (HORRIBLEVARS VAR₁ VAR_N) [File Package Command]
Like UGLYVARS, except structures may also contain circular pointers. Uses HPRINT (page 6.24). The values of VAR₁ VAR_N are printed in the same operation, so that they may contain pointers to common substructures.

UGLYVARS does not do any checking for circularities, which results in a large speed and internal-storage advantage over HORRIBLEVARS. Thus, if it is known that the data structures do *not* contain circular pointers, UGLYVARS should be used instead

File Package Commands

of HORRIBLEVARS.

(DECLARE: . FILEPK GCOMS/FLA GS) [File Package Command]

Normally expressions written onto a symbolic le are (1) evaluated when loaded; (2) copied to the compiled le when the symbolic le is compiled (see page 12.1); and (3) not evaluated at compile time. DECLARE: allows the user to override these defaults.

FILEPK GCOMS/FLA GS is a list of le package commands, possibly interspersed with “tags”. The output of those le package commands within FILEPK GCOMS/FLA GS is embedded in a DECLARE: expression, along with any tags that are specified. For example, (DECLARE: EVAL@COMPILE DONTCOPY (FNS) (PROP)) would produce (DECLARE: EVAL@COMPILE DONTCOPY (DEFINEQ) (PUTPROPS)). DECLARE: is *defined* as an nlambda nospread function, which processes its arguments by evaluating or not evaluating each expression depending on the setting of internal state variables. The initial setting is to evaluate, but this can be overridden by specifying the DONTEVAL@LOAD tag.

DECLARE: expressions are specially processed by the compiler. For the purposes of compilation, DECLARE: has two principal applications: (1) to specify forms that are to be evaluated at compile time, presumably to affect the compilation, e.g., to set up macros; and/or (2) to indicate which expressions appearing in the symbolic le are *not* to be copied to the output le. (Normally, expressions are *not* evaluated and *are* copied.) Each expression in CDR of a DECLARE: form is either evaluated/not-evaluated and copied/not-copied depending on the settings of two internal state variables, initially set for copy and not-evaluate. These state variables can be reset for the remainder of the expressions in the DECLARE: by means of the tags DONTCOPY, EVAL@COMPILE, etc.

The tags are:

EVAL@LOAD	
DOEVAL@LOAD	Evaluate the following forms when the le is loaded (unless overridden by DONTEVAL@LOAD).
DONTEVAL@LOAD	Do not evaluate the following forms when the le is loaded.
EVAL@LOADWHEN	This tag can be used to provide conditional evaluation. The value of the expression immediately following the tag determines whether or not to evaluate subsequent expressions when loading. EVAL@LOADWHEN T is equivalent to EVAL@LOAD
COPY	
DOCOPY	When compiling, copy the following forms into the compiled le.
DONTCOPY	When compiling, do not copy the following forms into the compiled le.
COPYWHEN	When compiling, if the next form evaluates to non-NIL, copy the following forms into the compiled le.

FILE PACKAGE

EVAL@COMPILE

DOEVAL@COMPILE When compiling, evaluate the following forms.

DONTEVAL@COMPILE

When compiling, do not evaluate the following forms.

EVAL@COMPILEWHEN

When compiling, if the next form evaluates to non-NIL, evaluate the following forms.

FIRST

For expressions that are to be copied to the compiled file, the tag FIRST can be used to specify that the following expressions in the DECLARE: are to appear at the front of the compiled file, before anything else except the FILECREATED expressions (see page 11.35). For example, (DECLARE: COPY FIRST (P (PRINT MESS1 T)) NOTFIRST (P (PRINT MESS2 T))) will cause (PRINT MESS1 T) to appear first in the compiled file, followed by any functions, then (PRINT MESS2 T).

NOTFIRST

Reverses the effect of FIRST.

The value of DECLARETAGSLST is a list of all the tags used in DECLARE: expressions. If a tag not on this list appears in a DECLARE: file package command, performs spelling correction using DECLARETAGSLST as a spelling list.

Note that the function LOADCOMP (page 11.6) provides a convenient way of obtaining information from the DECLARE: expressions in a file, without reading in the entire file. This information may be used for compiling other files.

(EXPORT COM₁ COM_N) [File Package Command]
This command is used for “exporting” definitions. Like COM, each of the commands COM₁ COM_N is interpreted as a file package command. The commands are also tagged in the file as being “exported” commands, for use with GATHEREXPORTS (see page 11.29).

(CONSTANTS VAR₁ VAR_N) [File Package Command]
Like VARS, for each VAR_i writes an expression to set its top level value when the file is loaded. Also writes a CONSTANTS expression to declare these variables as constants (see page 12.6). Both of these expressions are wrapped in a (DECLARE: EVAL@COMPILE) expression, so they can be used by the compiler.

Like VARS, VAR_i can be non-atomic, in which case it is interpreted as (VAR FORM), and passed to CONSTANTS (along with the variable being initialized to FORM).

(ORIGINAL COM₁ COM_N) [File Package Command]
Each of the commands COM_i will be interpreted as a file package command without regard to any file package macros (as defined by the MACRO property of the FILEPKGCOM function, page 11.32). Useful for redefining a built-in file package command in terms of itself.

Exporting Definitions

Note that some of the “built-in” le package commands are defined by le package macros, so interpreting them (or new user-defined le package commands) with ORIGINAL will fail. ORIGINAL was never intended to be used outside of a le package command macro.

(FILES . FILES/LISTS) [File Package Command]

Used to specify auxiliary les to be loaded in when the le is loaded. FILES/LISTS is a list of les, possibly interspersed with lists, which may be used to specify certain loading options. Within these lists, the following tokens are recognized:

The elements of the FILES command are the (name eld) of the les to load. There are actually several other ways to load in les; the FILES command interprets LISTP elements of the commands as a series of tokens which change its state. Those tokens can be:

FROM DIRECTORY	Pack the given directory onto the beginning of the le. For example, (FILES (FROM LISPUSERS) CJSYS). If this is not specified, the default is to use the same directory as the le containing the FILES command.
SOURCE	Load the source version of the le rather than the compiled version.
COMPILED	Load the compiled version of the le (the default).
LOAD	Load the le with by calling LOAD? (the default).
LOADCOMP	Load the le with LOADCOMP? rather than LOAD?. Automatically implies SOURCE.
LOADFROM	Load the le with LOADFROM rather than LOAD?.
SYSLOAD	Load the le with LDFLG = SYSOUT. This is mainly used when loading system les.
PROP	Load the le with LDFLG = PROP, so function definitions loaded will be stored on property lists.
ALLPROP	Load the le with LDFLG = ALLPROP, so both function definitions and variable values loaded will be stored on property lists.

These tokens can be joined together in a single list. For example, an actual command in the FTP package is:

```
(FILES (LOADCOMP) NET (SYSLOAD FROM LISPUSERS) CJSYS)
```

11.7.1 Exporting Definitions

When building a large system in Interlisp, it is often the case that there are record definitions, macros and the like that are needed by several different system les when running, analyzing and compiling the source

FILE PACKAGE

code of the system, but which are not needed for running the compiled code. By using the `DECLARE:` `le` package command with tag `DONTCOPY` (page 11.26), these definitions can be kept out of the compiled `les`, and hence out of the system constructed by loading the compiled `les` into Interlisp. This saves loading time, space in the resulting system, and whatever other overhead might be incurred by keeping those definitions around, e.g., burden on the record package to consider more possibilities in translating record accesses, or conflicts between system record fields and user record fields.

However, if the implementor wants to debug or compile code in the resulting system, the definitions are needed. And even if the definitions had been copied to the compiled `les`, a similar problem arises if one wants to work on system code in a regular Interlisp environment where none of the system `les` had been loaded. One could mandate that any definition needed by more than one `le` in the system should reside on a distinguished `le` of definitions, to be loaded into any environment where the system `les` are worked on. Unfortunately, this would keep the definitions away from where they logically belong. The `EXPORT` mechanism is designed to solve this problem.

To use the mechanism, the implementor identifies any definitions needed by `les` other than the one in which the definitions reside, and wraps the corresponding `le` package commands in the `EXPORT` `le` package command (page 11.27). Thereafter, `GATHEREXPORTS` can be used to make a single `le` containing all the exports.

```
(GATHEREXPORTS FROMFILES TOFILE FLG) [Function]
FROMFILES is a list of les containing EXPORT commands. GATHEREXPORTS
extracts all the exported commands from those les and produces a loadable le
TOFILE containing them. If FLG = EVAL, the expressions are evaluated as they
are gathered; i.e., the exports are effectively loaded into the current environment
as well as being written to TOFILE .
```

```
(IMPORTFILE FILE RETURNFLAG) [Function]
If RETURNFLAG is NIL, this loads any exported definitions from FILE into the
current environment. If RETURNFLAG is T, this returns a list of the exported
definitions (evaluable expressions) without actually evaluating them.
```

```
(CHECKIMPORTS FILES NOASKFLAG) [Function]
Checks each of the les in FILES to see if any exists in a version newer than
the one from which the exports in memory were taken (GATHEREXPORTS and
IMPORTFILE note the creation dates of the les involved), or if any le in the
list has not had its exports loaded at all. If there are any such les, the user is
asked for permission to IMPORTFILE each such le. If NOASKFLAG is non-NIL,
IMPORTFILE is performed without asking.
```

For example, suppose `le` `FOO` contains records `R1`, `R2`, and `R3`, macros `BAR` and `BAZ`, and constants `CON1` and `CON2`. If the definitions of `R1`, `R2`, `BAR`, and `BAZ` are needed by `les` other than `FOO`, then the `le` commands for `FOO` might contain the command

```
(DECLARE: EVAL@COMPILE DONTCOPY
  (EXPORT (RECORDS R1 R2)
          (MACROS BAR BAZ))
  (RECORDS R3)
  (CONSTANTS BAZ))
```

None of the commands inside this `DECLARE:` would appear on `FOO`'s compiled `le`, but `(GATHEREXPORTS '(FOO) 'MYEXPORTS)` would copy the record definitions for `R1` and `R2` and the macro definitions for

FileVars

BAR and BAZ to the le MYEXPORTS.

11.7.2 FileVars

In each of the le package commands described above, if the litatom * follows the command type,⁷ the form following the *, i.e., CADDR of the command, is evaluated and its value used in executing the command, e.g., (FNS * (APPEND FNS1 FNS2)). When this form is a litatom, e.g. (FNS * FOOFNS), we say that the variable is a “levar”. Note that (COMS * FORM) provides a way of *computing* what should be done by MAKEFILE.

Example:

```
_ (SETQ FOOFNS '(FOO1 FOO2 FOO3))
(FOO1 FOO2 FOO3)
_ (SETQ FOOCOMS
  '( (FNS * FOOFNS)
    (VARS FIE)
    (PROP MACRO FOO1 FOO2)
    (P (MOVD 'FOO1 'FIE1))))
_ (MAKEFILE 'FOO)
```

would create a le FOO containing:

```
(FILECREATED "time and date the le was made" . "other information")
(PRETTYCOMPRINT FOOCOMS)
(RPAQQ FOOCOMS ((FNS * FOOFNS) ))
(RPAQQ FOOFNS (FOO1 FOO3 FOO3))
(DEFINEQ "de nitions of FOO1, FOO2, and FOO3")
(RPAQQ FIE "value of FIE")
(PUTPROPS FOO1 MACRO PR OPV AL UE )
(PUTPROPS FOO2 MACRO PR OPV AL UE )
(MOVD (QUOTE FOO1) (QUOTE FIE1))
STOP
```

11.7.3 De ning New File Package Commands

A le package command is de ned by specifying the values of certain properties. The user can specify the various attributes of a le package command for a new command, or respecify them for an existing command. The following properties are used:

MACRO Defines how to dump the le package command. Used by MAKEFILE. Value is a pair (AR GS . COMS). The “arguments” to the le package command are substituted for AR GS throughout COMS , and the result treated as a list of le package commands. For example, following (FILEPKGCOM 'FOO 'MACRO '((X Y) .

⁷Except for the PROP and IFPROP commands, in which case the * follows the property name, e.g., (PROP MACRO * FOO MACROS).

FILE PACKAGE

(COMS)), the `le` package command `(FOO A B)` will cause `A` to be substituted for `X` and `B` for `Y` throughout `COMS`, and then `COMS` treated as a list of commands.

The substitution is carried out by `SUBPAIR` (page 2.24), so that the “argument list” for the macro can also be atomic. For example, if `(X . COMS)` was used instead of `((X Y) . COMS)`, then the command `(FOO A B)` would cause `(A B)` to be substituted for `X` throughout `COMS`.

Note: Filevars are evaluated *before* substitution. For example, if the literal `*` follows `NAME` in the command, `CADDR` of the command is evaluated substituting in `COMS`.

ADD

Specifies how (if possible) to add an instance of an object of a particular type to a given `le` package command. Used by `ADDTOFILE`. Value is `FN`, a function of three arguments, `COM`, a `le` package command `CAR` of which is `EQ` to `COMMANDNAME`, `NAME`, a typed object, and `TYPE`, its type. `FN` should return `T` if it (undoably) adds `NAME` to `COM`, `NIL` if not. If no `ADD` property is specified, then the default is (1) if `(CAR COM) = TYPE` and `(CADR COM) = *`, and `(CADDR COM)` is a levar (i.e. a literal atom), add `NAME` to the value of the levar, or (2) if `(CAR COM) = TYPE` and `(CADR COM)` is not `*`, add `NAME` to `(CDR COM)`.

Actually, the function is given a fourth argument, `NEAR`, which if non-`NIL`, means the function should try to add the item after `NEAR`. See discussion of `ADDTOFILES?`, page 11.8.

DELETE

Specifies how (if possible) to delete an instance of an object of a particular type from a given `le` package command. Used by `DELFROMFILES`. Value is `FN`, a function of three arguments, `COM`, `NAME`, and `TYPE`, same as for `ADD`. `FN` should return `T` if it (undoably) deletes `NAME` from `COM`, `NIL` if not. If no `DELETE` property is specified, then the default is (1) `(CAR COM) = TYPE` and `(CADR COM) = *`, and `(CADDR COM)` is a levar (i.e. a literal atom), and `NAME` is contained in the value of the levar, then remove `NAME` from the levar, or (2) if `(CAR COM) = TYPE` and `(CADR COM)` is not `*`, and `NAME` is contained in `(CDR COM)`, then remove `NAME` from `(CDR COM)`.

If `FN` returns the value of `ALL`, it means that the command is now “empty”, and can be deleted entirely from the command list.

CONTENTS

CONTAIN

Specifies whether an instance of an object of a given type is contained in a given `le` package command. Used by `WHEREIS` and `INFILECOMS?`. Value is `FN`, a function of three arguments, `COM`, a `le` package command `CAR` of which is `EQ` to `COMMANDNAME`, `NAME`, and `TYPE`. The interpretation of `NAME` is as follows: if `NAME` is `NIL`, `FN` should return a list of elements of type `TYPE` contained in `COM`. If `NAME` is `T`, `FN` should return `T` if there are *any* elements of type `TYPE` in `COM`. If `NAME` is an atom other than `T` or `NIL`, return `T` if `NAME` of type `TYPE` is contained in `COM`. Finally, if `NAME` is a list, return a list of those elements of type `TYPE` contained in `COM` that are also contained in `NAME`.

Note that it is sufficient for the `CONTENTS` function to simply return the list of items of type `TYPE` in command `COM`, i.e. it can in fact ignore the `NAME` argument. The `NAME` argument is supplied mainly for those situations where producing the

Functions for Manipulating File Command Lists

entire list of items involves significantly more computation or creates more storage than simply determining whether a particular item (or any item) of type `TYPE` is contained in the command.

If a `CONTENTS` property is specified and the corresponding function application returns `NIL` and `(CAR COM) = TYPE`, then the operation indicated by `NAME` is performed (1) on the value of `(CADDR COM)`, if `(CADR COM) = *`, otherwise (2) on `(CDR COM)`. In other words, by specifying a `CONTENTS` property that returns `NIL`, e.g. the function `NILL`, the user specifies that a `le` package command of name `FOO` produces objects of `le` package type `FOO` and only objects of type `FOO`.

If the `CONTENTS` property is not provided, the command is simply expanded according to its `MACRO` definition, and each command on the resulting command list is then interrogated.

Note that if `COMMANDNAME` is a `le` package command that is used frequently, its expansion by the various parts of the system that need to interrogate `les` can result in a large number of `CONSES` and garbage collections. By informing the `le` package as to what this command actually does and does not produce via the `CONTENTS` property, this expansion is avoided. For example, suppose the user has a `le` package command called `GRAMMARS` which dumps various property lists but no functions. Thus, the `le` package could ignore this command when seeking information about `FNS`.

The function `FILEPKGCOM` is used to define new `le` package commands, or to change the attributes of existing commands. Note that it is possible to redefine the attributes of system `le` package commands, such as `FNS` or `PROPS`, and to cause unpredictable results.

`(FILEPKGCOM COMMANDNAME PR OP1 VAL1 PR OPN VALN)` [NoSpread Function]

Nospread function for defining new `le` package commands, or changing attributes of existing `le` package commands. `PR OPi` is one of the property names described above; `VALi` is the value to be given that property of the `le` package command `COMMANDNAME`. Returns `COMMANDNAME`.

`(FILEPKGCOM COMMANDNAME PR OP)` returns the value of the property `PR OP`, without changing it.

`(FILEPKGTYPE COMMANDNAME)` returns an alist of all of the defined properties of `COMMANDNAME`, using the property names as keys.

11.8 FUNCTIONS FOR MANIPULATING FILE COMMAND LISTS

The following functions may be used to manipulate `le`coms. Note that the argument `COMS` does *not* have to correspond to the `le`coms for some `le`. For example, `COMS` can be the list of commands generated as a result of expanding a user defined `le` package command.

`(INFILECOMS? NAME TYPE COMS _)` [Function]

`COMS` is a list of `le` package commands, or a variable whose value is a list of `le` package commands. `TYPE` is a `le` package type. `INFILECOMS?` returns `T` if

FILE PACKAGE

`NAME` of type `TYPE` is “contained” in `COMS` .

If `NAME = NIL`, `INFILECOMS?` returns a list of all elements of type `TYPE` .

If `NAME = T`, `INFILECOMS?` returns `T` if there are *any* elements of type `TYPE` in `COMS` .

(`ADDTOFILE` `NAME` `TYPE` `FILE` _ _) [Function]
Adds `NAME` of type `TYPE` to the le package commands for `FILE`. Uses `ADDTOCOMS` and `MAKENEWCOM`. Returns `FILE`. `ADDTOFILE` is undoable.

(`DELFROMFILES` `NAME` `TYPE` `FILES`) [Function]
Deletes all instances of `NAME` of type `TYPE` from the lecoms for each of the les on `FILES`. If `FILES` is a non-NIL litatom, (`LIST FILES`) is used. `FILES = NIL` defaults to `FILELST`. Returns a list of les from which `NAME` was actually removed. Uses `DELFROMCOMS`. `DELFROMFILES` is undoable.

Note: Deleting a function will also remove the function from any `BLOCKS` declarations in the lecoms.

(`ADDTOCOMS` `COMS` `NAME` `TYPE` _ _) [Function]
Adds `NAME` as a `TYPE` to `COMS` , a list of le package commands or a variable whose value is a list of le package commands. Returns `NIL` if `ADDTOCOMS` was unable to find a command appropriate for adding `NAME` to `COMS` . `ADDTOCOMS` is undoable.

Note that the exact algorithm for adding commands depends the particular command itself. See discussion of the `ADD` property, in the description of `FILEPKGCOM`, page 11.32.

Note: `ADDTOCOMS` will not attempt to add an item to any command which is inside of a `DECLARE:` unless the user specified a specific name via the `LISTNAME` or `NEAR` option of `ADDTOFILES?`.

(`DELFROMCOMS` `COMS` `NAME` `TYPE`) [Function]
Deletes `NAME` as a `TYPE` from `COMS` . Returns `NIL` if `DELFROMCOMS` was unable to modify `COMS` to delete `NAME` . `DELFROMCOMS` is undoable.

(`MAKENEWCOM` `NAME` `TYPE` _ _) [Function]
Returns a le package command for dumping `NAME` of type `TYPE` . Uses the procedure described in the discussion of `NEWCOM`, page 11.20.

(`MOVETOFILE` `TOFILE` `NAME` `TYPE` `FROMFILE`) [Function]
Moves the definition of `NAME` as a `TYPE` from `FROMFILE` to `TOFILE` by modifying the le commands in the appropriate way (with `DELFROMFILES` and `ADDTOFILE`).

Note that if `FROMFILE` is specified, the definition will be retrieved from that le, even if there is another definition currently in the user’s environment.

(`FILECOMSLST` `FILE` `TYPE` _) [Function]
Returns a list of all objects of type `TYPE` in `FILE`.

`TYPE` can also be the name of a le package command. For example,

Symbolic File Format

(FILECOMSLST FILE 'BLOCKS) will return the list of all BLOCKS declaration in FILE. FILECOMSLST knows about expanding user defined le package commands.

(FILEFNSLST FILE) [Function]
Same as (FILECOMSLST FILE 'FNS).

(FILECOMS FILE TYPE) [Function]
Returns (PACK* FILE (OR TYPE 'COMS)). Note that (FILECOMS 'FOO) returns the listatom FOOCOMS, not the value of FOOCOMS.

(SMASHFILECOMS FILE) [Function]
Maps down (FILECOMSLST FILE 'FILEVARS) and sets to NOBIND all levars (see page 11.30), i.e. any variable used in a command of the form (COMMAND * VARIABLE). Also sets (FILECOMS FILE) to NOBIND. Returns FILE.

11.9 SYMBOLIC FILE FORMAT

The le package manipulates symbolic les in a particular format. This format is defined so that the information in the le is easily readable when the le is listed, as well as being easily manipulated by the le package functions. In general, there is no reason for the user to manually change the contents of a symbolic le. However, in order to allow users to extend the le package, this section describes some of the functions used to write symbolic les, and other matters related to their format.

(PRETTYDEF PR TTYFNS PR TTYFILE PR TTYCOMS REPRINTFNS SOUR CEFILE CHANGES) [Function]
Writes a symbolic le in PRETTYPRINT format for loading, using FILERDTBL as its readtable. PRETTYDEF returns the name of the symbolic le that was created.

PrettyDEF operates under a RESETLST (see page 9.19), so if an error occurs, or a control-D is typed, all les that PRETTYDEF has opened will be closed, the (partially complete) le being written will be deleted, and any undoable operations executed will be undone.⁸

PR TTYFNS is an optional list of function names. It is equivalent to including (FNS * PR TTYFNS) in the le package commands in PR TTYCOMS. PR TTYFNS is an anachronism from when PRETTYDEF did not use a list of le package commands, and should be specified as NIL.

PR TTYFILE is the name of the le on which the output is to be written. If PR TTYFILE = NIL, the primary output le is used. If PR TTYFILE is atomic the le is opened if not already open, and it becomes the primary output le. PR TTYFILE is closed at end of PRETTYDEF, and the primary output le is restored. Finally, if PR TTYFILE is a list, CAR of PR TTYFILE is assumed to be the le name, and is opened if not already open. In this case, the le is left open at end of PRETTYDEF.

⁸Since PRETTYDEF operates under a RESETLST, any RESETSAVEs executed in the le package commands will also be protected. For example, if one of the le package commands executes a (RESETSAVE (RADIX -8)), the RADIX will automatically be restored.

FILE PACKAGE

`PRETTYCOMS` is a list of `le` package commands interpreted as described on page 11.21. If `PRETTYCOMS` is atomic, its top level value is used and an `RPAQQ` is written which will set that atom to the list of commands when the `le` is subsequently loaded. A `PRETTYCOMPRINT` expression (see below) will also be written which informs the user of the named atom or list of commands when the `le` is subsequently loaded.⁹

`REPRINTFNS` and `SOURCEFILE` are for use in conjunction with remaking a `le` (see page 11.10). `REPRINTFNS` can be a list of functions to be prettyprinted, or `EXPRS`, meaning prettyprint all functions with `EXPR` definitions, or `ALL` meaning prettyprint all functions either defined as `EXPRS`, or with `EXPR` properties. Note that doing a remake with `REPRINTFNS = NIL` makes sense if there have been changes in the `le`, but not to any of the functions, e.g., changes to variables or property lists. `SOURCEFILE` is the name of the `le` from which to copy the definitions for those functions that are *not* going to be prettyprinted, i.e., those not specified by `REPRINTFNS`. `SOURCEFILE = T` means to use most recent version (i.e., highest number) of `PRETTYFILE`, the second argument to `PRETTYDEF`. If `SOURCEFILE` cannot be found, `PRETTYDEF` prints the message "FILE NOT FOUND, SO IT WILL BE WRITTEN ANEW", and proceeds as it does when `REPRINTFNS` and `SOURCEFILE` are both `NIL`.

`PRETTYDEF` calls `PRETTYPRINT` with its second argument `PRETTYDEFL G = T`, so whenever `PRETTYPRINT` starts a new function, it prints (on the terminal) the name of that function if more than 30 seconds (real time) have elapsed since the last time it printed the name of a function.

Note that normally if `PRETTYPRINT` is given a litem which is not defined as a function but is known to be on one of the `les` noticed by the `le` package, `PRETTYPRINT` will load in the definition (using `LOADFNS`) and print it. This is not done when `PRETTYPRINT` is called from `PRETTYDEF`.

(`PRINTFNS x _`) [Function]

`x` is a list of functions. `PRINTFNS` prettyprints a `DEFINEQ` expression that defines the functions to the primary output `le` using the primary readable. Used by `PRETTYDEF` to implement the `FNS le` package command.

(`PRINTDATE FILE CHANGES`) [Function]

Prints the `FILECREATED` expression at beginning of `PRETTYDEF` `les`. `CHANGES` used by the `le` package.

(`FILECREATED x`) [NLambda NoSpread Function]

Prints a message (using `LISPXPRT`) followed by the time and date the `le` was made, which is `(CAR x)`. The message is the value of `PRETTYHEADER`, initially "FILE CREATED". If `PRETTYHEADER = NIL`, nothing is printed. `(CDR x)` contains information about the `le`, e.g., full name, address of `le` map, list of changed items, etc. `FILECREATED` also stores the time and date the `le` was made

⁹In addition, if any of the functions in the `le` are `Nlambdas`, `PRETTYDEF` will automatically print a `DECLARE:` expression suitable for informing the compiler about these functions, in case the user recompiles the `le` without having first loaded the `nlambda` functions. See page 12.6.

Copyright Notices

on the property list of the `le` under the property `FILEDATES` and performs other initialization for the `le` package.

`(PRETTYCOMPRINT x)` [NLambda Function]
Prints `x` (unevaluated) using `LISPXPRINT`, unless `PRETTYHEADER = NIL`.

`PRETTYHEADER` [Variable]
Value is the message printed by `FILECREATED`. `PRETTYHEADER` is initially "FILE CREATED". If `PRETTYHEADER = NIL`, neither `FILECREATED` nor `PRETTYCOMPRINT` will print anything. Thus, setting `PRETTYHEADER` to `NIL` will result in "silent loads". `PRETTYHEADER` is reset to `NIL` during greeting (page 14.5).

`(FILECHANGES FILE TYPE)` [Function]
Returns a list of the changed objects of `le` package type `TYPE` from the `FILECREATED` expression of `FILE`. If `TYPE = NIL`, returns an alist of all of the changes, with the `le` package types as the `CARS` of the elements..

`(FILEDATE FILE _)` [Function]
Returns the `le` date contained in the `FILECREATED` expression of `FILE`.

11.9.1 Copyright Notices

The system has a facility for automatically printing a copyright notice near the front of `les`, right after the `FILECREATED` expression, specifying the years it was edited and the copyright owner. The format of the copyright notice is:

```
(* Copyright (c) 1981 by Foo Bars Corporation)
```

Once a `le` has a copyright notice then every version will have a new copyright notice inserted into the `le` without user intervention. (The copyright information necessary to keep the copyright up to date is stored at the end of the `le`.)

Any year the `le` has been edited is considered a "copyright year" and therefore kept with the copyright information. For example, if a `le` has been edited in 1981, 1982, and 1984, then the copyright notice would look like:

```
(* Copyright (c) 1981,1982,1984 by Foo Bars Corporation)
```

When a `le` is made, if it has no copyright information, the system will ask the user to specify the copyright owner (if `COPYRIGHTFLG = T`). The user may specify one of the names from `COPYRIGHTOWNERS`, or give one of the following responses:

- (1) Type a left-square-bracket. The system will then prompt for an arbitrary string which will be used as the owner-string
- (2) Type a right-square-bracket, which specifies that the user really does not want a copyright notice.
- (3) Type "NONE" which specifies that this `le` should never have a copyright notice.

For example, if `COPYRIGHTOWNERS` has the value

FILE PACKAGE

```
((BBN "Bolt Beranek and Newman Inc.")  
(XEROX "Xerox Corporation"))
```

then for a new le FOO the following interaction will take place:

```
Do you want to Copyright FOO? Yes  
Copyright owner: (user typed ?)  
one of:  
BBN - Bolt Beranek and Newman Inc.  
XEROX - Xerox Corporation  
NONE - no copyright ever for this file  
[ - new copyright owner -- type one line of text  
] - no copyright notice for this file now
```

Copyright owner: BBN

Then "Foo Bars Corporation" in the above copyright notice example would have been "Bolt Beranek and Newman Inc."

The following variables control the operation of the copyright facility:

COPYRIGHTFLG [Variable]

If COPYRIGHTFLG= NIL (default), the system will preserve old copyright information, but will not ask the user about copyrighting new les.

If COPYRIGHTFLG= T, then when a le is made, if it has no copyright information, the system will ask the user to specify the copyright owner.

If COPYRIGHTFLG= NEVER, the system will neither prompt for new copyright information nor preserve old copyright information.

COPYRIGHTOWNERS [Variable]

COPYRIGHTOWNERS is a list of entries of the form (KEY OWNERSTRING), where KEY is used as a response to ASKUSER and OWNERSTRING is a string which is the full identification of the owner.

DEFAULTCOPYRIGHTOWNER [Variable]

If the user does not respond in DWIMWAIT seconds to the copyright query, the value of DEFAULTCOPYRIGHTOWNER is used.

11.9.2 Functions Used Within Source Files

The following functions are normally only used within symbolic les, to set variable values, property values, etc. Most of these have special behavior depending on le package variables.

(RPAQ VAR VALUE) [NLambda Function]

An nlambda function like SETQ that sets the top level binding of VAR (unevaluated) to VALUE.

(RPAQQ VAR VALUE) [NLambda Function]

An nlambda function like SETQQ that sets the top level binding of VAR

File Maps

(unevaluated) to VALUE (unevaluated).

(RPAQ? VAR VALUE) [NLambda Function]
Similar to RPAQ, except that it does nothing if VAR already has a top level value other than NOBIND. Returns VALUE if VAR is reset, otherwise NIL.

RPAQ, RPAQQ, and RPAQ? generate errors if x is not a litatom. All are affected by the value of DFNFLG (page 5.9). If DFNFLG= ALLPROP (and the value of VAR is other than NOBIND), instead of setting x, the corresponding value is stored on the property list of VAR under the property VALUE. All are undoable.

(ADDTOVAR VAR X₁ X₂ ... X_N) [NLambda NoSpread Function]
Each X_i that is not a member of the value of VAR is added to it, i.e. after ADDTOVAR completes, the value of VAR will be (UNION (LIST X₁ X₂ ... X_N) VAR). ADDTOVAR is used by PRETTYDEF for implementing the ADDVARS command. It performs some le package related operations, i.e. “notices” that VAR has been changed. Returns the atom VAR (not the value of VAR).

(PUTPROPS ATM PROP₁ VAL₁ ... PROP_N VAL_N) [NLambda NoSpread Function]
NLambda nospread version of PUTPROP (none of the arguments are evaluated). For i= 1 .. N, puts property PROP_i value VAL_i on the property list of ATM. Performs some le package related operations, i.e., “notices” that the corresponding properties have been changed.

(SAVEPUT ATM PROP VAL) [Function]
Same as PUTPROP, but marks the corresponding property value as having been changed (used by the le package).

11.9.3 File Maps

A le map is a data structure which contains a symbolic ‘map’ of the contents of a le. Currently, this consists of the begin and end byte address (see GETFILEPTR, page 6.9) for each DEFINEQ expression in the le, the begin and end address for each function definition within the DEFINEQ, and the begin and end address for each compiled function.

MAKEFILE, PRETTYDEF, LOADFNS, RECOMPILE, and numerous other system functions depend heavily on the le map for efficient operation. For example, the le map enables LOADFNS to load selected function definitions simply by setting the le pointer to the corresponding address using SETFILEPTR, and then performing a single READ. Similarly, the le map is heavily used by the “remake” option of MAKEFILE (page 11.10): those function definitions that have been changed since the previous version are prettyprinted; the rest are simply copied from the old le to the new one, resulting in a considerable speedup.

Whenever a le is written by MAKEFILE, a le map for the new le is built. Building the map in this case essentially comes for free, since it requires only reading the current le pointer before and after each definition is written or copied. However, building the map does require that PRETTYPRINT *know* that it is printing a DEFINEQ expression. For this reason, the user should never print a DEFINEQ expression onto a le himself, but should instead always use the FNS le package command (page 11.22).

The le map is stored on the property list of the root name of the le, under the property FILEMAP. In addition, MAKEFILE writes the le map on the le itself. For cosmetic reasons, the le map is written as the last expression in the le. However, the *address* of the le map in the le is (over)written into the

FILE PACKAGE

FILECREATED expression that appears at the beginning of the `le` so that the `le` map can be rapidly accessed without having to scan the entire `le`. In most cases, `LOAD` and `LOADFNS` do not have to build the `le` map at all, since a `le` map will usually appear in the corresponding `le`, unless the `le` was written with `BUILDMAPFLG= NIL`, or was written outside of Interlisp.

Currently, `le` maps for *compiled* `les` are not written onto the `les` themselves. However, `LOAD` and `LOADFNS` will build maps for a compiled `le` when it is loaded, and store it on the property `FILEMAP`. Similarly, `LOADFNS` will obtain and use the `le` map for a compiled `le`, when available.

The use and creation of `le` maps is controlled by the following variables:

`BUILDMAPFLG` [Variable]

Whenever a `le` is read by `LOAD` or `LOADFNS`, or written by `MAKEFILE`, a `le` map is automatically built unless `BUILDMAPFLG= NIL`. (`BUILDMAPFLG` is initially `T`.)

While building the map will not help the `rst` reference to a `le`, it will help in future references. For example, if the user performs `(LOADFROM 'FOO)` where `FOO` does not contain a `le` map, the `LOADFROM` will be (slightly) slower than if `FOO` did contain a `le` map, but subsequent calls to `LOADFNS` for this version of `FOO` will be able to use the map that was built as the result of the `LOADFROM`, since it will be stored on `FOO`'s `FILEMAP` property.

`USEMAPFLG` [Variable]

If `USEMAPFLG= T` (the initial setting), the functions that use `le` maps will `rst` check the `FILEMAP` property to see if a `le` map for this `le` was previously obtained or built. If not, the `rst` expression on the `le` is checked to see if it is a `FILECREATED` expression that also contains the address of a `le` map. If the `le` map is not on the `FILEMAP` property or in the `le`, a `le` map will be built (unless `BUILDMAPFLG= NIL`).

If `USEMAPFLG= NIL`, the `FILEMAP` property and the `le` will not be checked for the `le` map. This allows the user to recover in those cases where the `le` and its map for some reason do not agree. For example, if the user uses a text editor to change a symbolic `le` that contains a map (not recommended), inserting or deleting just one character will throw that map `o`. The functions which use `le` maps contain various integrity checks to enable them to detect that something is wrong, and to generate the error `FILEMAP DOES NOT AGREE WITH CONTENTS OF FILE`. In such cases, the user can set `USEMAPFLG` to `NIL`, causing the map contained in the `le` to be ignored, and then reexecute the operation.

File Maps
